Abstract. A \( p \)-local finite group consists of a finite \( p \)-group \( S \), together with a pair of categories which encode “conjugacy” relations among subgroups of \( S \), and which are modelled on the fusion in a Sylow \( p \)-subgroup of a finite group. It contains enough information to define a classifying space which has many of the same properties as \( p \)-completed classifying spaces of finite groups. In this paper, we examine which subgroups control this structure. More precisely, we prove that the question of whether an abstract fusion system \( \mathcal{F} \) over a finite \( p \)-group \( S \) is saturated can be determined by just looking at smaller classes of subgroups of \( S \). We also prove that the homotopy type of the classifying space of a given \( p \)-local finite group is independent of the family of subgroups used to define it, in the sense that it remains unchanged when that family ranges from the set of \( \mathcal{F} \)-centric \( \mathcal{F} \)-radical subgroups (at a minimum) to the set of \( \mathcal{F} \)-quasicentric subgroups (at a maximum). Finally, we look at constrained fusion systems, analogous to \( p \)-constrained finite groups, and prove that they in fact all arise from groups.
does not depend directly on the structure of the ambient group. Many results in group theory, such as Alperin’s fusion theorem [Al] and the work by Alperin and Broué on fusion in block theory [AB], can be formulated in terms of fusion categories. One is thus led to search for an axiomatic definition of these concepts. The definition of a saturated fusion system $\mathcal{F}$ over a $p$-group $S$, generalizing $p$-fusion categories of finite groups, was first given by Puig [Pu2]. A simplified (but equivalent) definition of a saturated fusion system, along with an axiomatic definition of a “centric” linking system, was later given in [BLO2, §1]. Here, the word “centric” refers to the set of objects in the linking system, which will be described in Section 1. A $p$-local finite group is then defined to be a triple $(S, \mathcal{F}, \mathcal{L})$, where $S$ is a finite $p$-group, $\mathcal{F}$ is a saturated fusion system over $S$, and $\mathcal{L}$ is a centric linking system associated to $\mathcal{F}$. The classifying space of such a triple is the $p$-completed nerve $|\mathcal{L}|_p^\wedge$. For any $S \leq G$ as above, $(S, \mathcal{F}_S(G), \mathcal{L}_S(G))$ (where the categories are taken for appropriate families of subgroups) is a $p$-local finite group with classifying space $|\mathcal{L}_S(G)|_p^\wedge \approx BG^p$.

The main goal of this paper is to examine the role of the set $\mathcal{H}$ of subgroups of $S$ on which the fusion and linking systems are defined; i.e., to show when the set can be changed without changing $\mathcal{F}$ and $\mathcal{L}$ in an “essential” way. Related questions have been studied extensively when $\mathcal{F}$ comes from a finite group $G$, both in connection with the Alperin’s fusion theorem (cf. [Al] and [Pu1]) and more indirectly in connection with the study of homology decompositions (cf. [Dw1] and [Gr]). In a subsequent paper [BCGLO2], we use the tools developed in this paper to study the extension theory of fusion systems and $p$-local finite groups, in part motivated by our desire to develop more ways of constructing $p$-local finite groups that do not come from groups. Such “exotic” $p$-local finite groups do exist for all primes, and examples are given in [BLO2, §9], [RV], [LO], and [BM], but we still have no really good tools for constructing them, nor any sense of how frequently they occur.

We now describe the results of the paper in more detail. We refer the reader to Section 1 for the definitions of abstract saturated fusion systems and centric linking systems; and also of $\mathcal{F}$-centric and $\mathcal{F}$-radical subgroups for a fusion system $\mathcal{F}$ (analogous to the usual concepts of $p$-centric subgroups and radical $p$-subgroups of a finite group). However, the precise definitions will not be essential to follow this introductory discussion. We also refer the reader to the end of the introduction for a list of notation which will be used throughout the paper.

One of the most difficult problems, when constructing exotic fusion systems, is showing that the fusion system one has constructed satisfies the axioms of saturation (see Definition 1.3). This job is clearly simpler if one only needs to check the axioms on subgroups which are centric, rather than having to do so on all subgroups. The following theorem is used several times in our paper [BCGLO2], and can be used to shorten the proof of saturation of the exotic fusion systems in [BLO2, §9].

**Theorem A.** Let $\mathcal{F}$ be a fusion system over a finite $p$-group $S$, and assume that all morphisms in $\mathcal{F}$ are composites of restrictions of morphisms between $\mathcal{F}$-centric subgroups. If $\mathcal{F}$ satisfies the axioms of saturation (Definition 1.3) when applied to $\mathcal{F}$-centric subgroups of $S$, then $\mathcal{F}$ is saturated.

This theorem is stated more precisely, and in greater generality, in Theorem 2.2. There, we replace “$\mathcal{F}$-centric” subgroups in the above formulation by “any collection of subgroups containing all subgroups which are both $\mathcal{F}$-centric and $\mathcal{F}$-radical and is closed under $\mathcal{F}$-conjugacy”; but at the price of an additional hypothesis. As such, it can be thought of as a converse to Alperin’s fusion theorem for abstract fusion
systems (as shown in [Pu2, 2.13] and [BLO2, Theorem A.10]), which says that if $F$ is a saturated fusion system, then it is generated by restrictions of automorphisms of $F$-centric $F$-radical subgroups.

In many applications, it is useful to construct linking systems with respect to different sets of subgroups than the $F$-centric subgroups of $S$. If $G$ is a finite group, then we call a $p$-subgroup $P \leq G$ $p$-quasicentric if $O^p(C_G(P))$ has order prime to $p$; equivalently, if $BC_G(P)_{J_p}^p$ is the classifying space of some $p$-group. When $F$ is a saturated fusion system over a $p$-group $S$, then we make an analogous definition of an $F$-quasicentric subgroup of $S$ in Section 3. When $F$ is the fusion system of a block $b$ with defect group $S$, then the $F$-quasicentric subgroups of $S$ correspond to the nil-centralized pointed groups, in the sense of Puig [Pu3], which are associated to $b$.

Our next theorem shows that the homotopy type of the classifying space of a $p$-local finite group $(S, F, L)$ is also determined by a linking system based on any set of $F$-quasicentric subgroups of $S$ which contains at least those which are both $F$-centric and $F$-radical. This result can also be interpreted as a statement about homology decompositions for $p$-local finite groups, and as such is motivated by [Dw1, 1.20] and [Gr, Theorem 1.5]. It is restated and proved as Theorem 3.5, and is essential when studying “extensions” of $p$-local finite groups with $p$-group quotient in $[BCGLO2]$.

**Theorem B.** Let $(S, F, L)$ be a $p$-local finite group. Then there exists a category $L'$ containing $L$ as a full subcategory, whose objects are the $F$-quasicentric subgroups of $S$, and such that the inclusion of nerves $|L| \subseteq |L'|$ is a homotopy equivalence. Furthermore, if $H$ is any collection of $F$-quasicentric subgroups of $S$ containing all $P \leq S$ which are both $F$-centric and $F$-radical, and $L' \subseteq L'$ is the full subcategory whose objects are the subgroups in $H$, then the inclusions of $L' \subseteq L$ in $L'$ induce homotopy equivalences $|L'| \simeq |L'| \simeq |L|$.

We conclude this paper, in Section 4, with a very specialized family of examples: fusion systems whose entire structure is controlled by a single $p$-subgroup. If $G$ is a finite group which has no nontrivial normal subgroup of order prime to $p$, then $G$ is called $p$-constrained if there is a normal $p$-subgroup $P \triangleleft G$ such that $C_G(P) \leq P$; equivalently, such that $G/P$ can be identified (via conjugation) with a subgroup of $\text{Out}(P)$. In Section 4, we give an analogous definition of a constrained fusion system (Definition 4.1), and then prove the following proposition (restated as Proposition 4.3).

**Proposition C.** Let $F$ be a constrained saturated fusion system over a finite $p$-group $S$. Then there exists a unique $p'$-reduced $p$-constrained finite group $G$ such that $F = F_S(G)$.

For easy reference, we end the introduction with a list of notation and terminology which is used throughout the paper.

- $\text{Syl}_p(G)$ denotes the set of Sylow $p$-subgroups of $G$.
- $O_p(G)$ is the maximal normal $p$-subgroup of $G$.
- $O_{p'}(G)$ is the maximal normal subgroup of $G$ of order prime to $p$.
- $G$ is $p$-reduced ($p'$-reduced) if $O_p(G) = 1$ (if $O_{p'}(G) = 1$).
- $O^p(G)$ the minimal normal subgroup of $G$ of $p$-power index.
- $N_G(P, Q) = \{ x \in G \mid xPx^{-1} \leq Q \}$ (for $P, Q \leq G$).
- $c_x$ denotes conjugation by $x$ ($g \mapsto xgx^{-1}$).
We next specify certain collections of subgroups relative to a given fusion system. If
$F$ is a fusion system over a finite $p$-subgroup $S$, then two subgroups $P, Q \leq S$ are said to be $F$-conjugate if they are isomorphic as objects of the category $F$.

**Definition 1.2.** Let $F$ be a fusion system over a finite $p$-subgroup $S$.

- A subgroup $P \leq S$ is $F$-centric if $C_S(P') = Z(P')$ for all $P' \leq S$ which are $F$-conjugate to $P$.
- A subgroup $P \leq S$ is $F$-radical if $\text{Out}_F(P)$ is $p$-reduced; i.e., if $O_p(\text{Out}_F(P)) = 1$.

If $F = F_S(G)$ for some finite group $G$, then $P \leq S$ is $F$-centric if and only if $P$ is $p$-centric in $G$ (i.e., $Z(P) \in \text{Syl}_p(C_G(P))$), and $P$ is $F$-radical if and only if $N_G(P)/P \cdot C_G(P)$ is $p$-reduced.

The following additional definitions and conditions are needed in order for these systems to be very useful.

**Definition 1.3 ([Pu2], see [BLO2, Definition 1.2]).** Let $F$ be a fusion system over a
$p$-group $S$.

- A subgroup $P \leq S$ is fully centralized in $F$ if $|C_S(P)| \geq |C_S(P')|$ for all $P' \leq S$ which is $F$-conjugate to $P$.
- A subgroup $P \leq S$ is fully normalized in $F$ if $|N_S(P)| \geq |N_S(P')|$ for all $P' \leq S$ which is $F$-conjugate to $P$.
- $F$ is a saturated fusion system if the following two conditions hold:
(I) For all \( P \leq S \) which is fully normalized in \( \mathcal{F} \), \( P \) is fully centralized in \( \mathcal{F} \) and \( \text{Aut}_S(P) \in \text{Syl}_p(\text{Aut}_\mathcal{F}(P)) \).

(II) If \( P \leq S \) and \( \varphi \in \text{Hom}_\mathcal{F}(P,S) \) are such that \( \varphi P \) is fully centralized, and if we set
\[
N_\varphi = \{ g \in N_S(P) \mid \varphi g \varphi^{-1} \in \text{Aut}_S(\varphi P) \},
\]
then there is \( \overline{\varphi} \in \text{Hom}_\mathcal{F}(N_\varphi, S) \) such that \( \overline{\varphi}|_P = \varphi \).

If \( G \) is a finite group and \( S \in \text{Syl}_p(G) \), then the category \( \mathcal{F}_S(G) \) defined in the introduction is a saturated fusion system (see [BLO2, Proposition 1.3]).

We now turn to linking systems associated to abstract fusion systems.

**Definition 1.4** ([BLO2, Definition 1.7]). Let \( \mathcal{F} \) be a fusion system over the \( p \)-group \( S \). A centric linking system associated to \( \mathcal{F} \) is a category \( \mathcal{L} \) whose objects are the \( \mathcal{F} \)-centric subgroups of \( S \), together with a functor \( \pi: \mathcal{L} \longrightarrow \mathcal{F}^c \), and “distinguished” monomorphisms \( P \xrightarrow{\delta_P} \text{Aut}_\mathcal{L}(P) \) for each \( \mathcal{F} \)-centric subgroup \( P \leq S \), which satisfy the following conditions.

(A) \( \pi \) is the identity on objects. For each pair of objects \( P,Q \in \mathcal{L} \), \( Z(P) \) acts freely on \( \text{Mor}_\mathcal{L}(P,Q) \) by composition (upon identifying \( Z(P) \) with \( \delta_P(Z(P)) \leq \text{Aut}_\mathcal{L}(P) \)), and \( \pi \) induces a bijection
\[
\text{Mor}_\mathcal{L}(P,Q)/Z(P) \xrightarrow{\simeq} \text{Hom}_\mathcal{F}(P,Q).
\]

(B) For each \( \mathcal{F} \)-centric subgroup \( P \leq S \) and each \( x \in P \), \( \pi(\delta_P(x)) = c_x \in \text{Aut}_\mathcal{F}(P) \).

(C) For each \( f \in \text{Mor}_\mathcal{L}(P,Q) \) and each \( x \in P \), \( f \circ \delta_P(x) = \delta_Q(\pi f(x)) \circ f \).

A \( p \)-local finite group is defined to be a triple \( (S, \mathcal{F}, \mathcal{L}) \), where \( S \) is a finite \( p \)-group, \( \mathcal{F} \) is a saturated fusion system over \( S \), and \( \mathcal{L} \) is a centric linking system associated to \( \mathcal{F} \). The classifying space of the triple \( (S, \mathcal{F}, \mathcal{L}) \) is the \( p \)-completed nerve \( |\mathcal{L}|_p^\wedge \).

For any finite group \( G \) with Sylow \( p \)-subgroup \( S \), the category \( \mathcal{L}_S^c(G) \) defined in the introduction is easily seen to be a centric linking system associated to \( \mathcal{F}_S(G) \). Thus \( (S, \mathcal{F}_S(G), \mathcal{L}_S^c(G)) \) is a \( p \)-local finite group, with classifying space \( |\mathcal{L}_S^c(G)|_p^\wedge \simeq BG_p^\wedge \) (see [BLO1, Proposition 1.1]).

The following definitions are somewhat more specialized, and are translations to the setting of fusion systems of the concepts of a normal \( p \)-subgroup of a finite group, and of strongly and weakly closed subgroups.

**Definition 1.5.** Let \( \mathcal{F} \) be a saturated fusion system over a \( p \)-group \( S \). Then for any normal subgroup \( Q \triangleleft S \),

(a) \( Q \) is strongly closed in \( \mathcal{F} \) if no element of \( Q \) is \( \mathcal{F} \)-conjugate to an element of \( S \setminus Q \);

(b) \( Q \) is weakly closed in \( \mathcal{F} \) if no other subgroup of \( S \) is \( \mathcal{F} \)-conjugate to \( Q \);

(c) \( Q \) is normal in \( \mathcal{F} \) if each morphism \( \alpha \in \text{Hom}_\mathcal{F}(P,P') \) in \( \mathcal{F} \) extends to a morphism \( \overline{\alpha} \in \text{Hom}_\mathcal{F}(PQ,P'Q) \) such that \( \overline{\alpha}(Q) = Q \).

Equivalently, \( Q \triangleleft S \) is normal in \( \mathcal{F} \) if and only if the normalizer fusion system \( N_\mathcal{F}(Q) \) is equal to \( \mathcal{F} \) as fusion systems over \( S \) (see [BLO2, Definition 6.1]). The next proposition, which is motivated by [Pu1, Proposition IV.2], gives two equivalent conditions for a subgroup to be normal in \( \mathcal{F} \).
Proposition 1.6. Let $\mathcal{F}$ be a fusion system over $S$. Then the following conditions on a subgroup $Q \leq S$ are equivalent:

(a) $Q$ is normal in $\mathcal{F}$.
(b) $Q$ is strongly closed in $\mathcal{F}$ and is contained in all $\mathcal{F}$-radical subgroups of $S$.
(c) $Q$ is weakly closed in $\mathcal{F}$ and is contained in all $\mathcal{F}$-radical subgroups of $S$.

Proof. Assume first that $Q$ is normal in $\mathcal{F}$. In particular, if an element $x \in Q$ is $\mathcal{F}$-conjugate to an element $y \in S \setminus Q$, then the isomorphism in $\mathcal{F}$ from $\langle x \rangle$ to $\langle y \rangle$ extends to a morphism $Q = \langle Q, x \rangle \longrightarrow \langle Q, y \rangle$. But such a morphism clearly cannot send $Q$ to itself. Thus $Q$ is strongly closed in $\mathcal{F}$. If $P \leq S$ does not contain $Q$, then $N_{\mathcal{F}}(P)/P$ is a nontrivial $p$-subgroup of ${\rm Out}_\mathcal{F}(P)$, which is in fact normal there. To see normality notice that if $\alpha \in {\rm Aut}_\mathcal{F}(P)$ then $\alpha$ extends to $\tilde{\alpha} \in {\rm Aut}_\mathcal{F}(PQ)$ since $Q$ normal in $\mathcal{F}$, so for all $x \in N_{\mathcal{F}}(P)$ we have $\alpha x \alpha^{-1} = (\tilde{\alpha} c \tilde{\alpha}^{-1})|_P = c_{\tilde{\alpha}(x)} \in {\rm Aut}_\mathcal{F}(PQ)$. Hence such a subgroup $P$ cannot be $\mathcal{F}$-radical. Thus, all $\mathcal{F}$-radical subgroups of $S$ contain $Q$. This shows $(a) \implies (b)$.

Condition $(b)$ clearly implies $(c)$, and so it remains to show $(c) \implies (a)$. Assume that $Q$ is weakly closed in $\mathcal{F}$, and that all $\mathcal{F}$-radical subgroups contain $Q$. Then by Alperin’s fusion theorem, each morphism in $\mathcal{F}$ is a composite of morphisms, each of which is the restriction of a morphism between subgroups containing $Q$, and which necessarily sends $Q$ to itself (since $Q$ is weakly closed). In other words, each $\varphi \in {\rm Hom}_\mathcal{F}(P, P')$ extends to a morphism $\bar{\varphi} \in {\rm Hom}_\mathcal{F}(PQ, P'Q)$ which sends $Q$ to itself, and hence $Q$ is normal in $\mathcal{F}$. \qed

2. CENTRIC AND RADICAL SUBGROUPS DETERMINE SATURATION

Given a fusion system which is not known to come from a group (or a block), it turns out to be difficult in general to show that it is saturated when using the definition directly. This is one of the obstacles one encounters when trying to construct $p$-local finite groups which do not come from groups.

The main result of this section, Theorem 2.2, says that it suffices to check the axioms of saturation on the centric subgroups, in the sense that any fusion system which satisfies these axioms for its centric subgroups generates a saturated fusion system in a way made precise below. In fact, our result is stronger than that. We prove that it suffices to check the axioms of saturation on those subgroups which are centric and radical, and a much weaker condition on the centric subgroups which are not radical.

Before stating the main results, we make some definitions.

Definition 2.1. Let $\mathcal{F}$ be any fusion system over a finite $p$-group $S$, and let $\mathcal{H}$ be a set of subgroups of $S$ closed under conjugation.

(a) $\mathcal{F}$ is $\mathcal{H}$-generated if every morphism in $\mathcal{F}$ is a composite of restrictions of morphisms in $\mathcal{F}$ between subgroups in $\mathcal{H}$.
(b) $\mathcal{F}$ is $\mathcal{H}$-saturated if conditions (I) and (II) hold in $\mathcal{F}$ for all subgroups $P \in \mathcal{H}$.

In terms of these definitions, Alperin’s fusion theorem for abstract fusion systems (in the form shown in [BLO2, Theorem A.10]) can be reformulated by saying that if $\mathcal{F}$ is a
saturated fusion system over \( S \), and \( \mathcal{H} \) is the family of \( \mathcal{F} \)-centric, \( \mathcal{F} \)-radical subgroups of \( S \), then \( \mathcal{F} \) is \( \mathcal{H} \)-generated.

Our main result in this section can be thought of as a converse to this form of the fusion theorem. In practice, it often simplifies the task of deciding whether a fusion system is saturated or not. As one example, the proof of [BLO2, Proposition 9.1] — the proof that the fusion systems constructed there are saturated — becomes far simpler when we can use Theorem 2.2, applied with \( \mathcal{H} \) the set of \( \mathcal{F} \)-centric subgroups of \( S \).

**Theorem 2.2.** Let \( \mathcal{F} \) be a fusion system over a finite \( p \)-group \( S \) and let \( \mathcal{H} \) be a set of subgroups of \( S \) closed under conjugation in \( \mathcal{F} \) that contains all \( \mathcal{F} \)-centric, \( \mathcal{F} \)-radical subgroups of \( S \). Assume that \( \mathcal{F} \) is \( \mathcal{H} \)-generated and \( \mathcal{H} \)-saturated, and that

\[(*) \quad \text{each } \mathcal{F} \text{-conjugacy class of subgroups of } S \text{ which are } \mathcal{F} \text{-centric but not in } \mathcal{H} \text{ contains at least one subgroup } P \text{ such that } \text{Out}_S(P) \cap O_p(\text{Out}_\mathcal{F}(P)) \neq 1.\]

Then \( \mathcal{F} \) is saturated.

Note that the condition that \( \mathcal{H} \) contain all \( \mathcal{F} \)-centric, \( \mathcal{F} \)-radical subgroups of \( S \) is in fact implied by (*), but we keep it in the statement for the sake of emphasis.

We first discuss the relation between conditions (I) and (II) in Definition 1.3, and certain other, similar conditions on fusion systems. We recall the definition of \( N_\varphi \) for any given \( \varphi \in \text{Mor}_\mathcal{F}(P,Q) \),

\[N_\varphi = \{ x \in N_S(P) \mid \varphi x \varphi^{-1} \in \text{Aut}_S(\varphi(P)) \}.\]

**Lemma 2.3.** Let \( \mathcal{F} \) be a fusion system over a \( p \)-group \( S \), and let \( \mathcal{H} \) be a set of subgroups of \( S \) closed under \( \mathcal{F} \)-conjugacy. Consider the following conditions on \( \mathcal{F} \):

- \((I)_\mathcal{H}\): For each fully normalized subgroup \( P \in \mathcal{H} \), \( P \) is fully centralized, and \( \text{Aut}_S(P) \in \text{Syl}_p(\text{Aut}_\mathcal{F}(P)) \).
- \((I')_\mathcal{H}\): Each \( P \in \mathcal{H} \) is \( \mathcal{F} \)-conjugate to a fully centralized subgroup \( P' \in \mathcal{H} \) such that \( \text{Aut}_S(P') \in \text{Syl}_p(\text{Aut}_\mathcal{F}(P')) \).
- \((II)_\mathcal{H}\): For each \( P \in \mathcal{H} \) and each \( \varphi \in \text{Hom}_\mathcal{F}(P,S) \) such that \( \varphi(P) \) is fully centralized in \( \mathcal{F} \), \( \varphi \) extends to a morphism \( \tilde{\varphi} \in \text{Hom}_\mathcal{F}(N_\varphi,S) \).
- \((IIA)_\mathcal{H}\): Each \( \mathcal{F} \)-conjugacy class \( \mathcal{P} \subseteq \mathcal{H} \) contains a fully normalized subgroup \( \tilde{P} \in \mathcal{P} \) with the following property: for all \( P \in \mathcal{P} \), there exists \( \varphi \in \text{Hom}_\mathcal{F}(N_S(P), N_S(\tilde{P})) \) such that \( \varphi(P) = \tilde{P} \).
- \((IIB)_\mathcal{H}\): For each fully normalized subgroup \( \tilde{P} \in \mathcal{H} \) and each \( \varphi \in \text{Aut}_\mathcal{F}(\tilde{P}) \), there is a morphism \( \tilde{\varphi} \in \text{Hom}_\mathcal{F}(N_\varphi, N_S(\tilde{P})) \) which extends \( \varphi \).

Then

- (a) \( (I)_\mathcal{H} \iff (I')_\mathcal{H} \); and
- (b) \( (I)_\mathcal{H} + (II)_\mathcal{H} \implies (IIA)_\mathcal{H} + (IIB)_\mathcal{H} \implies (II)_\mathcal{H} \).

**Proof.** (a) Condition \((I)_\mathcal{H}\) clearly implies \((I')_\mathcal{H}\), since every \( P \leq S \) is conjugate to a fully normalized subgroup. To see the converse, assume \( P \in \mathcal{H} \) is fully normalized. By \((I')_\mathcal{H}\) we can choose \( P' \in \mathcal{H} \) which is \( \mathcal{F} \)-conjugate to \( P \), fully centralized, and satisfies
\[ \text{Aut}_S(P') \in \text{Syl}_P(\text{Aut}_F(P')). \]

Then

\[ |\text{Aut}_S(P')| \cdot |C_S(P')| = |N_S(P')| \leq |N_S(P)| \]

\[ = |\text{Aut}_S(P)| \cdot |C_S(P)| \leq |\text{Aut}_S(P')| \cdot |C_S(P')| : \]

the first inequality holds since \( P \) is fully normalized, and the second by the assumptions on \( P' \). Thus all of these inequalities are equalities, and so \( P \) is fully centralized and \( \text{Aut}_S(P) \in \text{Syl}_p(\text{Aut}_F(P)) \).

(b) Assume \( (I)_H \) and \( (II)_H \) hold; we next prove that this implies \( (IIA)_H \) and \( (IIB)_H \).

We first check condition \( (IIA)_H \). Let \( \hat{\varphi} = \iota_\hat{P} \circ \varphi \) where \( \iota_\hat{P} \) is the inclusion of \( \hat{P} \) in \( S \). Since \( \hat{P} \) is fully normalized, condition \( (I)_H \) implies that \( \hat{P} \) is also fully centralized. By condition \( (II)_H \), \( \hat{\varphi} \) extends to \( \bar{\varphi} \in \text{Hom}_F(N_{\hat{\varphi}}, S) \), where

\[ N_{\hat{\varphi}} = \{ g \in N_S(\hat{P}) \mid \hat{\varphi} c_g \hat{\varphi}^{-1} \in \text{Aut}_S(\hat{P}) \} = \{ g \in N_S(\hat{P}) \mid \varphi c_g \varphi^{-1} \in \text{Aut}_S(\hat{P}) \} = N_{\varphi}. \]

Furthermore, \( \text{Im}(\bar{\varphi}) \leq N_S(\hat{P}) \), since \( \hat{P} \triangleleft N_{\hat{\varphi}} \).

Next we check that \( (IIA)_H \) holds. Fix an \( F \)-conjugacy class \( P \subset H \), and choose a fully normalized subgroup \( \hat{P} \subset P \). Since \( (I)_H \) holds, \( \hat{P} \) is also fully centralized, and \( \text{Aut}_S(\hat{P}) \in \text{Syl}_p(\text{Aut}_F(\hat{P})) \). Thus for any \( P \in \mathcal{P} \) and any \( \varphi \in \text{Iso}_F(P, \hat{P}) \), there exists \( \chi \in \text{Aut}_F(P) \) such that \( \varphi \chi \text{Aut}_S(P) \chi^{-1} \varphi^{-1} \leq \text{Aut}_S(\hat{P}) \).

Then

\[ N_{\varphi\chi} \overset{\text{def}}{=} \{ g \in N_S(P) \mid \varphi \chi c_g \chi^{-1} \varphi^{-1} \in \text{Aut}_S(\hat{P}) \} = N_S(P), \]

and hence the morphism \( \varphi \chi \) extends to \( \bar{\varphi} \in \text{Hom}_F(N_S(P), S) \) by \( (II)_H \). Then \( \bar{\varphi}(P) = \varphi \chi(P) = \hat{P} \), and hence \( \text{Im}(\bar{\varphi}) \leq N_S(\hat{P}) \).

It remains to prove the last implication. Assume \( (IIA)_H \) and \( (IIB)_H \); we must prove \( (II)_H \). Fix \( P \in H \) and \( \varphi \in \text{Hom}_F(P, S) \) such that \( P' \overset{\text{def}}{=} \varphi(P) \) is fully centralized in \( F \). Using \( (IIA)_H \), choose a fully normalized subgroup \( \hat{P} \) which is \( F \)-conjugate to \( P, P' \), and morphisms

\[ \psi \in \text{Hom}_F(N_S(P), N_S(\hat{P})) \quad \text{and} \quad \psi' \in \text{Hom}_F(N_S(P'), N_S(\hat{P})) \]

such that \( \psi(P) = \psi'(P') = \hat{P} \). Set \( \bar{\varphi} = (\psi'|P') \circ \varphi \circ (\psi|P)^{-1} \in \text{Aut}_F(\hat{P}) \).

For each \( x \in N_{\varphi} \), there exists \( y \in N_S(P') \) such that \( \varphi c_x \varphi^{-1} = c_y \) as elements of \( \text{Aut}(P') \). Then as automorphisms of \( \hat{P} \), \( \bar{\varphi} c_{(x)} \bar{\varphi}^{-1} = c_{\psi(y)} \). This shows that \( \psi(N_{\varphi}) \leq N_{\hat{\varphi}} \).

By \( (IIB)_H \), \( \bar{\varphi} \) extends to a morphism \( \hat{\varphi} \in \text{Hom}_F(N_{\bar{\varphi}}, N_S(\hat{P})) \).

Now fix \( x \in N_{\varphi} \), and let \( y \in N_S(P') \) be such that \( \varphi c_x \varphi^{-1} = c_y \) as elements of \( \text{Aut}(P') \). The elements \( \bar{\varphi} \psi(x), \psi'(y) \in N_S(\hat{P}) \) induce the same conjugation action on \( \hat{P} \), and thus differ by an element in \( C_S(\hat{P}) \). Also, since \( P' \) is fully centralized, \( \psi'(C_S(P')) = C_S(\hat{P}) \), and hence

\[ \bar{\varphi} \psi(x) \in \psi'(y) \cdot C_S(\hat{P}) = \psi'(y \cdot C_S(P')) \leq \psi'(N_S(P')). \]

Thus \( \bar{\varphi} \psi(N_{\varphi}) \leq \psi'(N_S(P')) \), and so \( \varphi \circ \psi \) factors through some \( \bar{\varphi} \in \text{Hom}_F(N_{\varphi}, N_S(P')) \) which extends \( \varphi \). This finishes the proof of condition \( (II)_H \). \( \square \)

As an immediate consequence of Lemma 2.3, we obtain the following alternative characterization of the conditions of saturation: a fusion system \( F \) over \( S \) is saturated if and only if it satisfies the conditions \( (I')_H \), \( (IIA)_H \) and \( (IIB)_H \) where \( H \) is the set of all subgroups \( P \leq S \).
Notation. Following the notation introduced in Lemma 2.3 for the conditions stated there, we also write \((-)_Q\) or \((-)_\mathcal{H}\) for \((-)_\mathcal{H}\) when \(\mathcal{H} = \{Q\}\) or \(\mathcal{H} = \{P \mid Q \leq P \leq S\}\), respectively. Given a fusion system \(\mathcal{F}\) over \(S\), let \(S\) be the set of all subgroups of \(S\). For \(P \leq S\), let \(S_{\geq P} \supseteq S_{\geq P}\) be the sets of subgroups of \(S\) which contain, or strictly contain, \(P\).

We will now prove two lemmas which allow us to prove Theorem 2.2 by induction on the number of \(\mathcal{F}\)-conjugacy classes of subgroups of \(S\) not in \(\mathcal{H}\).

Lemma 2.4. Let \(\mathcal{F}\) be a fusion system over a finite \(p\)-group \(S\), and let \(\mathcal{H}\) be a set of subgroups of \(S\) closed under conjugacy. Let \(\mathcal{P}\) be a conjugacy class of subgroups of \(S\) which is maximal among those not in \(\mathcal{H}\). Assume \(\mathcal{F}\) is \(\mathcal{H}\)-generated and \(\mathcal{H}\)-saturated. Then the following hold for any \(P \in \mathcal{P}\) which is fully normalized in \(\mathcal{F}\):

(a) \(N_{\mathcal{F}}(P)\) is \(S_{\geq P}\)-saturated.

(b) Each \(\varphi \in \text{Aut}_{\mathcal{F}}(P)\) is a composite of restrictions of morphisms in \(N_{\mathcal{F}}(P)\) between subgroups strictly containing \(P\).

(c) \(\mathcal{F}\) is \((\mathcal{H} \cup \mathcal{P})\)-saturated if \(N_{\mathcal{F}}(P)\) is \(S_{\geq P}\)-saturated.

Proof. By a proper \(\mathcal{P}\)-pair will be meant a pair \((Q, P)\), where \(P \leq Q \leq N_S(P)\) and \(P \in \mathcal{P}\). Two proper \(\mathcal{P}\)-pairs \((Q, P)\) and \((Q', P')\) will be called \(\mathcal{F}\)-conjugate if there is an isomorphism \(\varphi \in \text{Iso}_{\mathcal{F}}(Q, Q')\) such that \(\varphi(P) = P'\). A proper \(\mathcal{P}\)-pair \((Q, P)\) will be called fully normalized if \(|N_{\mathcal{F}}(Q)| \geq |N_{\mathcal{F}}(P')|\) for all \((Q', P')\) in the same \(\mathcal{F}\)-conjugacy class.

The proof of the lemma is based on the following statements, whose proof will be carried out in Steps 1 to 4.

1. If \((Q, P)\) is a fully normalized proper \(\mathcal{P}\)-pair, then \(Q\) is fully centralized in \(\mathcal{F}\) and \(\text{Aut}_{N_S(P)}(Q) \in \text{Syl}_p(\text{Aut}_{N_{\mathcal{F}}(P)}(Q))\).

2. For each proper \(\mathcal{P}\)-pair \((Q, P)\), and each fully normalized proper \(\mathcal{P}\)-pair \((Q', P')\) which is \(\mathcal{F}\)-conjugate to \((Q, P)\), there is some \(\psi \in \text{Hom}_{\mathcal{F}}(N_{N_S(P)}(Q), N_{N_S(P')}(Q'))\) such that \(\psi(P) = P'\) and \(\psi(Q) = Q'\).

3. There is a subgroup \(\bar{P} \in \mathcal{P}\) which is fully centralized in \(\mathcal{F}\), and which has the property that for all \(P \in \mathcal{P}\), there is a morphism \(\varphi \in \text{Hom}_{\mathcal{F}}(N_S(P), N_S(\bar{P}))\) such that \(\varphi(P) = \bar{P}\).

4. Let \((Q, P)\) be a proper \(\mathcal{P}\)-pair such that \(P\) is fully normalized in \(\mathcal{F}\). If \(Q\) is fully normalized in \(N_{\mathcal{F}}(P)\), then \((Q, P)\) is fully normalized. If \(Q\) is fully centralized in \(N_{\mathcal{F}}(P)\), then \(Q\) is fully centralized in \(\mathcal{F}\).

Note that point (3) implies that \(\bar{P}\) is fully normalized in \(\mathcal{F}\), and that any other \(P' \in \mathcal{P}\) which is fully normalized in \(\mathcal{F}\) has the same properties.

Assuming points (1)–(4) have been shown, the lemma is proven as follows:

(a) We show that conditions (I) and (II) hold in \(N_{\mathcal{F}}(P)\) for all \(Q \in S_{\geq P}\). If \(Q \geq P\) is fully normalized in \(N_{\mathcal{F}}(P)\), then the proper \(\mathcal{P}\)-pair \((Q, P)\) is fully normalized by (4), and hence condition (I) holds in \(N_{\mathcal{F}}(P)\) by (1). It remains to show condition (II). Also, by (4) again, if \(P \subseteq Q \subseteq N_S(P)\) and \(Q\) is fully centralized in \(N_{\mathcal{F}}(P)\), then it is fully centralized in \(\mathcal{F}\). Hence (II) holds automatically for morphisms \(\varphi \in \text{Hom}_{N_S(P)}(Q, N_S(P))\), since it holds in \(\mathcal{F}\).
(b) Fix \( \varphi \in \operatorname{Aut}_F(P) \). Since \( F \) is \( H \)-generated, there are subgroups
\[
P = P_0, P_1, \ldots, P_k = P \quad \text{in} \quad P,
\]
and morphisms \( \varphi_i \in \operatorname{Hom}_F(Q_i, S) \) \( (0 \leq i \leq k - 1) \), such that \( \varphi_i(P_i) = P_{i+1} \) and \( \varphi = \varphi_{k-1} \circ \cdots \circ \varphi_0 \). Upon replacing each \( Q_i \) by \( N_{Q_i}(P_i) \gtrsim P_i \), we can assume that \( Q_i \leq N_S(P_i) \). By (3), there are morphisms \( \chi_i \in \operatorname{Hom}_F(N_S(P_i), N_S(P)) \) for each \( i \) such that \( \chi_i(P_i) = P \), where we take \( \chi_0 = \chi_k \) to be the identity. Upon replacing each \( \varphi_i \) by \( \chi_i \circ \varphi_i \circ \chi_i^{-1} \in \operatorname{Hom}_F(\chi_i(Q_i), S) \), we can arrange that \( P_i = P \) for all \( i \). Thus \( \varphi \) is a composite of restrictions of morphisms in \( N_F(P) \) between subgroups strictly containing \( P \).

(c) Assume that \( N_F(P) \) is \( S_{\geq P} \)-saturated. By Lemma 2.3, it is enough to check that Conditions (I')\( _P \), (IIA)\( _P \), and (IIB)\( _P \) are satisfied in \( F \). Condition (IIA)\( _P \) follows from point (3). Since \( \operatorname{Aut}_F(P) = \operatorname{Aut}_{N_F(P)}(P) \), it is clear that Condition (IIB)\( _P \) holds in \( F \). Finally, since \( \operatorname{Aut}_{S}(P) = \operatorname{Aut}_{N_S(P)}(P) \), and since the properties of \( \tilde{P} \) as described in point (3) hold for every fully normalized subgroup, (I)\( _P \) also holds, and this proves that \( F \) is \( (H \cup P) \)-saturated.

In order to finish the proof, it remains to prove points (1)–(4).

**Step 1:** For any proper \( P \)-pair \((Q, P)\), let \( K_P \leq \operatorname{Aut}(Q) \) be defined by
\[
K_P = \{ \varphi \in \operatorname{Aut}(Q) \mid \varphi(P) = P \}.
\]

If the pair \((Q, P)\) is fully normalized, then \( Q \) is fully \( K_P \)-normalized in \( F \) in the sense of [BLO2, Definition A.1]. Hence by [BLO2, Proposition A.2(a)], \( Q \) is fully centralized and
\[
\operatorname{Aut}_{N_S(P)}(Q) = \operatorname{Aut}_{S}(Q) \cap K_P \in \operatorname{Syl}_p(\operatorname{Aut}_F(Q) \cap K_P) = \operatorname{Syl}_p(\operatorname{Aut}_{N_F(P)}(Q)).
\]
More precisely, this follows from the proof of [BLO2, Proposition A.2], where we need only know that \( F \) satisfies the axioms of saturation on subgroups containing \( Q \) and its conjugates.

**Step 2:** Let \((Q', P')\) be any fully normalized proper \( P \)-pair of subgroups of \( S \) which is \( F \)-conjugate to \((Q, P)\). Let \( \varphi \in \operatorname{Iso}_F(Q, Q') \) such that \( \varphi(P) = P' \). Since \((Q', P')\) is fully normalized, \( Q' \) is fully centralized and \( \operatorname{Aut}_{N_S(P')(Q')} \in \operatorname{Syl}_p(\operatorname{Aut}_{N_F(P')}(Q')) \) by (I).

Since \( \varphi \operatorname{Aut}_{N_S(P)(Q)} \varphi^{-1} \) is a \( p \)-subgroup of \( \operatorname{Aut}_{N_F(P')(Q')}(Q') \), there is some morphism \( \alpha \in \operatorname{Aut}_{N_F(P')(Q')}(Q') \) such that
\[
\alpha \varphi \operatorname{Aut}_{N_S(P)(Q)} \varphi^{-1} \alpha^{-1} \leq \operatorname{Aut}_{N_S(P')(Q')}.
\]
Since \( F \) is \( H \)-saturated, \( \alpha \varphi \) extends to a morphism \( \tilde{\alpha \varphi} \in \operatorname{Hom}_F(N_{\alpha \varphi}, S) \) by (II)\( _Q \), where
\[
N_{\alpha \varphi} = \{ x \in N_S(Q) \mid \alpha \varphi x \alpha \varphi^{-1} \alpha^{-1} \in \operatorname{Aut}_S(Q') \} \geq N_{N_S(P)}(Q).
\]
Set \( \psi = \tilde{\alpha \varphi}|_{N_{N_S(P)}(Q)} \in \operatorname{Hom}_F(N_{N_S(P)}(Q), S) \). By construction, \( \operatorname{Im}(\psi) \leq N_{N_S(P)}(Q') \).

Moreover \( \psi|_Q = \alpha \varphi|_Q, \psi|_P = \alpha \varphi|_P \), and hence \( \psi(P) = P' \) and \( \psi(Q) = Q' \).

**Step 3:** We first show, for any \( P, P' \in P \), that there are \( P'' \in P \) and morphisms \( \psi \in \operatorname{Hom}_F(N_S(P), N_S(P'')) \) and \( \psi' \in \operatorname{Hom}_F(N_S(P'), N_S(P'')) \), such that \( \psi(P) = P'' = \psi'(P') \).

Let \( \xi = (P = P_0, Q_0, \varphi_0; P_1, Q_1, \varphi_1; \ldots; P_{k-1}, Q_{k-1}, \varphi_{k-1}; P_k = P') \)
such that $P_i \leq Q_i \leq N_S(P_i)$, $\varphi_i \in \text{Hom}_F(Q_i, N_S(P_{i+1}))$, and $\varphi_i(P_i) = P_{i+1}$. Let $\mathcal{T}_r \subseteq \mathcal{T}$ be the subset of those $\xi$ for which there is no $1 \leq i \leq k - 1$ such that $Q_i = N_S(P_i) = \varphi_{i-1}(Q_{i-1})$. Let $\mathcal{T} \overset{R}{\to} \mathcal{T}_r$ be the “reduction” map, which removes any $P_i$ such that $Q_i = N_S(P_i) = \varphi_{i-1}(Q_{i-1})$ (and replaces $\varphi_{i-1}$ and $\varphi_i$ by their composite).

Define

$$I(\xi) = \{0 \leq i \leq k - 1 \mid Q_i \leq N_S(P_i) \text{ and } \varphi_i(Q_i) \leq N_S(P_{i+1})\}.$$ 

If $\xi \in \mathcal{T}$ and $I(\xi) \neq \emptyset$, define

$$\lambda(\xi) = \min_{i \in I(\xi)} [Q_i : P_i] \geq p.$$ 

The main observation needed to prove point (3) is that there exists an element $\xi \in \mathcal{T}_r$ such that $I(\xi) = \emptyset$. Note first that $\mathcal{T} \neq \emptyset$, since $\mathcal{F}$ is $\mathcal{H}$-generated (and since $Q \supseteq P$ implies $N_Q(P) \supseteq P$). Hence (by the existence of the retraction functor $R$) $\mathcal{T}_r \neq \emptyset$.

Fix an element $\xi \in \mathcal{T}_r$ such that $I(\xi) \neq \emptyset$. We will construct $\tilde{\xi} \in \mathcal{T}_r$ such that either $I(\tilde{\xi}) = \emptyset$, or $\lambda(\tilde{\xi}) > \lambda(\xi)$. For each $i \in I(\xi)$, choose a fully normalized proper $\mathcal{P}$-pair $(Q_i', P_i')$ which is $\mathcal{F}$-conjugate to $(Q_i, P_i)$, and apply (2) to choose homomorphisms

$$\psi_i \in \text{Hom}_F(N_{N_S(P_i)}(Q_i), S) \text{ and } \psi_i' \in \text{Hom}_F(N_{N_S(P_{i+1})}(\varphi_i(Q_i)), S)$$

such that $\psi_i(P_i) = \psi_i'(P_{i+1}) = P_i''$ and $\psi_i(Q_i) = \psi_i'(Q_{i+1}) = Q_i''$. Set

$$\tilde{Q}_i = N_{N_S(P_i)}(Q_i) \supseteq Q_i \text{ and } \tilde{Q}_i' = \psi_i'(N_{N_S(P_{i+1})}(\varphi_i(Q_i))) \supseteq \psi_i'(Q_i).$$

Note that if $(Q, P)$ is a proper $\mathcal{P}$-pair with $P \leq Q \leq N_S(P)$, then $N_{N_S(P)}(Q) \geq Q$. Thus upon replacing the sequence $(P_i, Q_i, \varphi_i; P_{i+1})$ in $\xi$ by

$$(P_i, \tilde{Q}_i, \psi_i; P_i', \tilde{Q}_i', (\psi_i')^{-1}; P_{i+1})$$

and similarly for the other components of $I(\xi)$, we obtain a new element $\xi' \in \mathcal{T}$, such that either $I(\xi') = \emptyset$ or $\lambda(\xi') > \lambda(\xi)$ (by construction $[\tilde{Q}_i : P_i'] > [Q_i : P_i]$ and $[\tilde{Q}_i' : P_i''] > [Q_i : P_i]$). Then $\tilde{\xi} = R(\xi') \in \mathcal{T}_r$ is also such that either $I(\tilde{\xi}) = \emptyset$ or $\lambda(\tilde{\xi}) > \lambda(\xi)$.

Since the function $\lambda$ is bounded above, it follows by induction that there is $\xi \in \mathcal{T}_r$ such that $I(\xi) = \emptyset$. Write

$$\xi = (P_0, Q_0, \varphi_0; \cdots; P_{k-1}, Q_{k-1}, \varphi_{k-1}; P_k) \in \mathcal{T}_r \quad (P_0 = P, \ P_k = P').$$

The assumption $I(\xi) = \emptyset$ implies that for each $i$, either $Q_i = N_S(P_i)$ (hence $|N_S(P_i)| \leq |N_S(P_{i+1})|)$, or $\varphi_i(Q_i) = N_S(P_{i+1})$ (hence $|N_S(P_i)| \geq |N_S(P_{i+1})|)$.

Thus when $\xi \in \mathcal{T}_r$, there is no $1 \leq i \leq k - 1$ such that $|N_S(P_i)| < |N_S(P_{i-1})|$ and also $|N_S(P_i)| < |N_S(P_{i+1})|$. So if we choose $0 \leq j \leq k$ such that $|N_S(P_j)|$ is maximal, then

$$|N_S(P_j)| \leq |N_S(P_i)| \leq |N_S(P_2)| \leq \cdots \leq |N_S(P_j)|,$$

and

$$|N_S(P_j)| \geq |N_S(P_{j-1})| \geq \cdots \geq |N_S(P_{k-1})| \geq |N_S(P')|.$$ 

Since $I(\xi) = \emptyset$, this implies that $Q_i = N_S(P_i)$ for all $i < j$, and that $\varphi_i(Q_i) = N_S(P_{i+1})$ for all $j \leq i \leq k - 1$. So upon setting $P'' = P_j$, we obtain homomorphisms

$$\psi = \varphi_{j-1} \circ \cdots \circ \varphi_0 \in \text{Hom}_F(N_S(P), N_S(P''))$$

and

$$\psi' = (\varphi_{k-1} \circ \cdots \circ \varphi_j)^{-1} \in \text{Hom}_F(N_S(P'), N_S(P''))$$

such that $\psi(P) = P'' = \psi'(P')$. 

This was shown for an arbitrary pair of subgroups \(P, P' \in \mathcal{P}\). By successively applying the above construction to the subgroups in the conjugacy class \(\mathcal{P}\), it now follows easily that there is some \(\widehat{P} \in \mathcal{P}\) such that for all \(P \in \mathcal{P}\), there is a morphism \(\varphi \in \text{Hom}_\mathcal{F}(N_S(P), N_S(\widehat{P}))\) such that \(\varphi(P) = \widehat{P}\). Note that \(\widehat{P}\) is fully normalized since \(N_S(\widehat{P})\) contains an injective image of any other \(N_S(P)\) for \(P \in \mathcal{P}\). For the same reason, \(\widehat{P}\) is fully centralized in \(\mathcal{F}\): its centralizer contains an injective image of the centralizer of any other subgroup in the conjugacy class \(\mathcal{P}\).

**Step 4:** Fix a proper \(\mathcal{P}\)-pair \((Q, P)\) such that \(P\) is fully normalized in \(\mathcal{F}\). By (3), the pair \((N_S(P), P)\) is \(\mathcal{F}\)-conjugate to \((N_S(\widehat{P}), \widehat{P})\). Hence for every \(P' \in \mathcal{P}\), there is \(\psi \in \text{Hom}_\mathcal{F}(N_S(P'), N_S(P))\) such that \(\psi(P') = P\).

Assume \(Q\) is fully normalized in \(N_\mathcal{F}(P)\). Let \((Q', P')\) be any proper \(\mathcal{P}\)-pair \(\mathcal{F}\)-conjugate to \((Q, P)\), and choose \(\psi\) as above. Set \(Q'' = \psi(Q')\). Then \(\psi\) sends \(N_{N_S(P)}(Q')\) injectively into \(N_{N_S(P)}(Q'')\). So

\[
|N_{N_S(P)}(Q')| \leq |N_{N_S(P)}(Q'')| \leq |N_{N_S(P)}(Q)|;
\]

where the last inequality holds since \(Q\) is fully normalized in \(N_\mathcal{F}(P)\). This shows that the pair \((P, Q)\) is fully normalized.

Finally, assume \(Q\) is fully centralized in \(N_\mathcal{F}(P)\), and let \(Q'\) be any other subgroup in the \(\mathcal{F}\)-conjugacy class of \(Q\). Fix \(\varphi \in \text{Iso}_\mathcal{F}(Q, Q')\), and set \(P' = \varphi(P)\). Again, choose \(\psi\) as above, and set \(Q'' = \psi(Q')\). Then \(|C_S(Q')| \leq |C_S(Q'')|\) since \(\psi\) sends the first subgroup injectively into the second, and \(|C_S(Q'')| \leq |C_S(Q)|\) since \(Q\) is fully centralized in \(N_\mathcal{F}(P)\) and the pairs \((Q, P)\) and \((Q'', P)\) are \(\mathcal{F}\)-conjugate. This shows that \(Q\) is fully centralized in \(\mathcal{F}\).

Lemma 2.4 reduces the problem of proving \(\mathcal{P}\)-saturation, for an \(\mathcal{F}\)-conjugacy class \(\mathcal{P}\), to the case where \(\mathcal{P} = \{P\}\) and \(P\) is normal in \(\mathcal{F}\). This case is handled in the next lemma.

**Lemma 2.5.** Let \(\mathcal{F}\) be a fusion system over a \(p\)-group \(S\). Assume that \(P \trianglelefteq S\) is normal in \(\mathcal{F}\), and that \(\mathcal{F}\) is \(S_{>P}\)-generated and \(S_{>P}\)-saturated. Assume furthermore that either \(P\) is not \(\mathcal{F}\)-centric, or \(\text{Out}_S(P) \cap O_p(\text{Out}_\mathcal{F}(P)) \neq 1\). Then \(\mathcal{F}\) is \(S_{\geq P}\)-saturated.

**Proof.** Define

\[
P^* = \{x \in S \mid c_x \in O_p(\text{Aut}_\mathcal{F}(P))\}.
\]

It follows from the definition that \(P^* \trianglelefteq S\), and we claim that \(P^*\) is strongly closed in \(\mathcal{F}\). Assume that \(x \in P^*\) is \(\mathcal{F}\)-conjugate to \(y \in S\). Since \(P\) is normal in \(\mathcal{F}\), there exists \(\psi \in \text{Hom}_\mathcal{F}(\langle x, P \rangle, \langle y, P \rangle)\) which satisfies \(\psi(P) = P\) and \(\psi(x) = y\). In particular, \(\psi \circ c_x \circ \psi^{-1} = c_y\). It follows that \(y \in P^*\), since \(c_y \in O_p(\text{Aut}_\mathcal{F}(P))\).

Note also that \(P^* \supseteq C_S(P)P\). Hence by the assumption \(\text{Out}_S(P) \cap O_p(\text{Out}_\mathcal{F}(P)) \neq 1\) if \(P\) is \(\mathcal{F}\)-centric, or by definition if \(P\) is not \(\mathcal{F}\)-centric, \(P \not\subseteq P^*\) in all cases.

Since \(\mathcal{F}\) is assumed to be \(S_{>P}\)-saturated, we need only to prove conditions (I)\(_P\) and (II)\(_P\). We first prove that these conditions follow from the following statement:

(\(*\star\)) each \(\varphi \in \text{Aut}_\mathcal{F}(P)\) extends to some \(\overline{\varphi} \in \text{Aut}_\mathcal{F}(P^*)\).

Since \(P\) is normal in \(\mathcal{F}\), it is the only subgroup in its \(\mathcal{F}\)-conjugacy class, and hence it is fully centralized and fully normalized. It is also clear that \(P^*\) is fully normalized in \(\mathcal{F}\), since \(P^* \trianglelefteq S\). Hence \(\text{Aut}_S(P^*) \subseteq \text{Syl}_p(\text{Aut}_\mathcal{F}(P^*))\) by (I)\(_{>P}\). The restriction map
from Aut\(_F(P^*)\) to Aut\(_F(P)\) is surjective by (**) and so Aut\(_S(P)\) ∈ Syl\(_p\)(Aut\(_F(P)\)). Therefore condition (I)\(_P\) holds.

Next we prove condition (II)\(_P\): that each automorphism \(\varphi \in \text{Aut}_F(P)\) extends to a morphism defined on \(N_\varphi\). By (**) \(\varphi\) extends to some \(\psi \in \text{Aut}_F(P^*)\). Consider the groups of automorphisms

\[
K = \{ \chi \in \text{Aut}_S(P^*) \mid \chi \big|_P = c_x \text{ some } x \in N_\varphi \} \\
K_0 = \{ \chi \in \text{Aut}_F(P^*) \mid \chi \big|_P = \text{Id}_P \} < \text{Aut}_F(P^*)
\]

By definition, for all \(x \in N_\varphi\), we have \((\psi c_x \psi^{-1}) \big|_P = \chi \big|_P\) for some \(\chi \in \text{Aut}_S(P^*)\). In other words, as subgroups of Aut\((P^*)\),

\[
\psi K \psi^{-1} \leq \{ \psi c_x \psi^{-1} \mid x \in N_\varphi \} \cdot (\psi K_0 \psi^{-1}) \leq \text{Aut}_S(P^*) \cdot (\psi K_0 \psi^{-1}).
\]

In general, if \(S \in \text{Syl}_p(G), H < G\), and \(P \leq SH\) is a \(p\)-subgroup, then there is \(x \in H\) such that \(P \leq xSx^{-1}\). Applied to this situation (with \(G = \text{Aut}_F(P^*), S = \text{Aut}_S(P^*), H = \psi K_0 \psi^{-1}\), and \(P = \psi K \psi^{-1}\)), we see that there is \(\chi \in K_0\) such that

\[
(\psi \chi)K(\psi \chi)^{-1} = (\psi \chi \psi^{-1})(\psi K \psi^{-1})(\psi \chi \psi^{-1})^{-1} \leq \text{Aut}_S(P^*)
\]

Also, \(P^*\) is fully centralized in \(F\) by (I)\(_P\), since \(P^*\) is fully normalized. So by (II)\(_P\), \(\psi \chi \in \text{Aut}_F(P^*)\) extends to a morphism \(\overline{\varphi}\) defined on \(N_\chi^K(P^*) \supseteq N_\varphi\), and \(\overline{\varphi} \big|_P = \psi \big|_P = \varphi\) since \(\chi \big|_P = \text{Id}_P\).

In order to finish the proof, it remains to prove (**) since any \(\varphi \in \text{Aut}_F(P)\) is a composite of automorphisms of \(P\) which extend to strictly larger subgroups, it suffices to show (**) when \(\varphi\) itself extends to \(\overline{\varphi} \in \text{Iso}_F(Q_1, Q_2)\), where \(Q_1 \supseteq P\). Note that

\[
\overline{\varphi}(Q_1 \cap P^*) = Q_2 \cap P^* \tag{1}
\]

since \(P^*\) is strongly closed in \(F\).

We show (**) by induction on the index \([P^*, P^* \cap Q_1] = [P^*, P^* \cap Q_2]\). If this index is 1, i.e., if \(Q_1 \supseteq P^*\), then \(\overline{\varphi}(P^*) = P^*\) by (1), and hence \(\overline{\varphi} \equiv \overline{\varphi} \big|_{P^*}\) lies in \(\text{Aut}_F(P^*)\) and extends \(\varphi\).

Now assume \(Q_1 \not\supset P^*\); let \(Q_3\) be any subgroup \(F\)-conjugate to \(Q_1\) and \(Q_2\) and fully normalized in \(F\), and fix \(\varphi \in \text{Iso}_F(Q_2, Q_3)\). Upon replacing \(\overline{\varphi}\) by \(\psi\) and by \(\psi \circ \overline{\varphi}\), we are reduced to proving the result when the target group is fully normalized. So assume \(Q_2\) is fully normalized (and hence, by (I)\(_P\), fully centralized).

This time, consider the groups of automorphisms

\[
K = \{ \chi \in \text{Aut}_F(Q_2) \mid \chi \big|_P \in \text{O}_p(\text{Aut}_F(P)) \} \\
K_0 = \{ \chi \in \text{Aut}_F(Q_2) \mid \chi \big|_P = \text{Id}_P \}.
\]

Both \(K\) and \(K_0\) are normal subgroups of \(\text{Aut}_F(Q_2)\). Also, \(K/K_0\) is a \(p\)-group, since there is a monomorphism \(K/K_0 \rightarrow \text{O}_p(\text{Aut}_F(Q_2))\). So any two Sylow \(p\)-subgroups of \(K\) are conjugate by an element of \(K_0\).

Now, \(\text{Aut}_{P^*}(Q_1)\) is a \(p\)-subgroup of \(\text{Aut}_F(Q_1)\), all of whose elements restrict to elements of \(\text{O}_p(\text{Aut}_F(P))\). Hence \(\overline{\varphi} \text{Aut}_{P^*}(Q_1) \overline{\varphi}^{-1}\) is a \(p\)-subgroup of \(K\). Since \(Q_2\) is fully normalized, \(\text{Aut}_S(Q_2) \in \text{Syl}_p(\text{Aut}_F(Q_2))\), and hence \(\text{Aut}_{P^*}(Q_2) = K \cap \text{Aut}_S(Q_2)\) is a Sylow \(p\)-subgroup of \(K\). Thus there is \(\chi \in K_0\) such that

\[
\chi \overline{\varphi} \text{Aut}_{P^*}(Q_1) \overline{\varphi}^{-1} \chi^{-1} \leq \text{Aut}_{P^*}(Q_2).
\]
In particular, $N_{P_{Q_1}}(Q_1) \leq N_{\overline{\gamma}}$. Since $Q_2$ is fully centralized, condition $(II)_{P}$ now implies that $\overline{\varphi}$ extends to a morphism $\overline{\varphi}' \in \text{Hom}_F(Q_1, N_S(Q_2))$, where $Q_1' = N_{P_{Q_1}}(Q_1)$. Furthermore, $\overline{\varphi}'|_P = \overline{\varphi}|_P$ since $\chi \in K_0$.

By assumption, $P^*Q_1 \geq Q_1$, and so $Q_1' = N_{P^*Q_1}(Q_1) \supseteq Q_1$. Also, $Q_1'$ is generated by $Q_1$ and $Q_1 \cap P^*$ since $Q_1 \leq Q_1' \leq P^*Q_1$. Hence $Q_1 \cap P^* \supseteq Q_1 \cap P^*$.

This shows that $[P^*:P^* \cap Q_1] < [P^*P^* \cap Q_1]$, and so $(**)$ now follows by the induction hypothesis. 

We are now ready to prove Theorem 2.2.

**Proof of Theorem 2.2.** We are given a set $\mathcal{H}$ of subsets of $S$, closed under $F$-conjugacy, such that $\mathcal{F}$ is $\mathcal{H}$-generated and $\mathcal{H}$-saturated, and such that condition

\[ (*) \quad \text{each } F \text{-conjugacy class of subgroups of } S \text{ which are } F \text{-centric but not in } \mathcal{H} \text{ contains at least one subgroup } P \text{ such that } \text{Out}_S(P) \cap \text{Out}_F(P) \neq 1. \]

holds. We will prove, by induction on the number of $F$-conjugacy classes of subgroups of $S$ not in $\mathcal{H}$, that $\mathcal{F}$ is saturated. If $\mathcal{H}$ contains all subgroups, then we are done. Otherwise, let $P \in \mathcal{P}$ be any $F$-conjugacy class of subgroups of $S$ which is maximal among those not in $\mathcal{H}$. We will show that $\mathcal{F}$ is also $(\mathcal{H} \cup \mathcal{P})$-saturated. Since $\mathcal{F}$ is clearly $(\mathcal{H} \cup \mathcal{P})$-generated, the result then follows by the induction hypothesis.

By Lemma 2.4, for any fully normalized subgroup $P \in \mathcal{P}$, the normalizer fusion system $N_F(P)$ is $S_{\geq P}$-saturated, and $\text{Aut}_F(P)$ is generated by restrictions of morphisms in $N_F(P)$ between subgroups of $N_S(P)$ which strictly contain $P$.

Let $\mathcal{F}_0$ be the fusion system over $S_0 \overset{\text{def}}{=} N_S(P)$ generated by the restriction of $N_F(P)$ to $S_{\geq P}$, that is, the smallest fusion system over $S_0$ for which morphisms between subgroups in $S_{\geq P}$ are the same as those in $N_F(P)$. Then $\text{Aut}_{\mathcal{F}_0}(P) = \text{Aut}_F(P)$, and $\mathcal{F}_0$ is $S_{\geq P}$-saturated and $S_{\geq P}$-generated. Also, by the assumption $(*)$, either $P$ is not centric in $\mathcal{F}$ (hence not centric in $\mathcal{F}_0$), or $\text{Out}_{S_0}(P) \cap \text{Out}_F(P) \neq 1$. Then $\mathcal{F}_0$ is $S_{\geq P}$-saturated by Lemma 2.5, and so $\mathcal{F}$ is $(\mathcal{H} \cup \mathcal{P})$-saturated by Lemma 2.4 again.

We end this section with a description of a example which shows why the assumption $(*)$ in Theorem 2.2 $(\text{Out}_{S_0}(P) \cap \text{Out}_F(P) \neq 1$ if $P$ is not centric) is needed. We use the following standard notation: if $k$ is a finite field, and $n \geq 1$, then $\Sigma L_n(k)$ denotes the semidirect product of $SL_n(k)$ with the group of field automorphisms of $k$. This group has an obvious action on the vector space $k^n$ and on the projective space $\mathbb{P}(k^n)$. It is not hard to see that $\Sigma L_2(\mathbb{F}_4) \cong S_5$: via its permutation action on the five points in $\mathbb{P}(\mathbb{F}_4^2)$.

Let $\Gamma = \mathbb{F}_4 \rtimes S_5$, where $S_5$ acts on $\mathbb{F}_4^2$ via the above isomorphism. Note that $\Gamma$ can be identified with the subgroup of $\Sigma L_3(\mathbb{F}_4)$ generated by matrices with bottom row $(0, 0, 1)$ and the field automorphism. Therefore $\Gamma$ acts faithfully on $P = \mathbb{F}_4^2$.

We are going to define a fusion system $\mathcal{F}$ over $S = P \rtimes S'$, where $S' = \langle (1, 2), (4, 5) \rangle \leq S_5 \leq \Gamma$. Consider the following subgroups of $S$: $Q_1 = P \rtimes \langle (1, 2) \rangle$, $Q_2 = P \rtimes \langle (4, 5) \rangle$, and $Q_3 = P \rtimes \langle (1, 2)(4, 5) \rangle$. We regard all of these groups, including $\Gamma$, as subgroups of $P \rtimes \Gamma$.

To define the morphisms in the fusion system $\mathcal{F}$, let $x \in O_2(\Gamma) \cong \mathbb{F}_4^2$ be the element of order two which centralizes $S'$, and consider the subgroups $R_1 = \langle S', (3, 4, 5) \rangle$, $R_2 = \langle S', (1, 2, 3) \rangle$, and $R_2' = xR_2x^{-1}$. Set $\text{Out}_{\mathcal{F}}(S) = 1$, $\text{Aut}_{\mathcal{F}}(Q_1) = \text{Aut}_{P_{R_1}}(Q_1)$,
Aut\(_F\)(Q_2) = \text{Aut}_{P_{R_2}}(Q_2), \text{ and } \text{Aut}_{\mathcal{F}}(Q_3) = \text{Aut}_S(Q_3). \) All other morphisms in the fusion system are restrictions of the ones just described. Note in particular that \(\text{Out}_{\mathcal{F}}(Q_1) \cong S_3, \text{Out}_{\mathcal{F}}(Q_2) \cong S_3, \text{ and } \text{Aut}_{\mathcal{F}}(P) = \langle R_1, R_2' \rangle = \Gamma. \) The last equality holds since \(\langle P, R_1, R_2' \rangle / P = \langle S', (1 2 3), (3 4 5) \rangle = S_5; \text{ and } \langle R_1, R_2' \rangle \) cannot be a splitting of \(\Gamma / P \) in \(\Gamma \) since any splitting containing \(S'\) must be \(P\)-conjugate to the given \(S_5 \leq \Gamma; \) so \(\langle R_1, R_2' \rangle \cap P \neq 1, \text{ and } \langle R_1, R_2' \rangle \supseteq P \) since \(P\) is irreducible as an \(S_5\)-representation.

Consider the set of subgroups \(\mathcal{H} = \{S, Q_1, Q_2, Q_3\}. \) It follows from the above description of morphisms in \(\mathcal{F}\) that the subgroups in \(\mathcal{H}\) are the only \(\mathcal{F}\)-centric, \(\mathcal{F}\)-radical subgroups. Also, \(\mathcal{F}\) is \(\mathcal{H}\)-generated by construction, and one can check that \(\mathcal{F}\) is \(\mathcal{H}\)-saturated. But \(\mathcal{F}\) is not saturated, since axiom (I)\(_P\) fails: \(\text{Aut}_S(P) \notin \text{Syl}_2(\text{Aut}_{\mathcal{F}}(P))\) since \(\text{Aut}_S(P) \cong C_2^2\) and \(\text{Aut}_{\mathcal{F}}(P) \cong \Gamma. \) (One can also show that (II)\(_P\) fails.) Note that \(\text{Out}_S(P) \cap O_2(\text{Out}_{\mathcal{F}}(P)) = S' \cap O_2(\Gamma) = 1, \) so Condition (*) in Theorem 2.2 does not hold.

3. Expanding and restricting the classifying space: quasicentric subgroups

The goal of this section is to show how the centric linking system of a \(p\)-local finite group \((S, \mathcal{F}, \mathcal{L})\) can be extended to a larger category or restricted to a smaller one without changing the homotopy type of the nerve of \(\mathcal{L}\).

One motivation for doing this is a problem which frequently occurs when trying to construct maps between \(p\)-local finite groups. A functor between fusion systems need not send centric subgroups to centric subgroups, in which case it cannot be lifted to a functor between associated centric linking systems. One could try to get around this by extending the linking systems to include all subgroups as objects. There is in fact a natural extension of the linking system to a category whose objects are all subgroups of \(S\), but in general the homotopy type of the \(p\)-completed nerve is not preserved by this extension.

We introduce here the collection of \(\mathcal{F}\)-quasicentric subgroups, which contains the centric subgroups and supports an associated linking system \(\mathcal{L}^q\) with properties analogous to those of the centric one. The important fact proved in this section is that the nerve of \(\mathcal{L}^q\) is homotopy equivalent to \(|\mathcal{L}|\). Moreover, any full subcategory of \(\mathcal{L}^q\) whose object set contains all subgroups which are centric and radical also has nerve homotopy equivalent to \(|\mathcal{L}|\).

**Definition 3.1.** Let \(\mathcal{F}\) be a saturated fusion system over a \(p\)-group \(S\). A subgroup \(P \leq S\) is called \(\mathcal{F}\)-quasicentric if for each \(P'\) which is fully centralized in \(\mathcal{F}\) and \(\mathcal{F}\)-conjugate to \(P\), the centralizer system \(C_{\mathcal{F}}(P')\) is the fusion system of the \(p\)-group \(C_S(P')\).

Equivalently, when \(\mathcal{F}\) is a saturated fusion system over \(S\), a subgroup \(P \leq S\) is \(\mathcal{F}\)-quasicentric if there is no \(Q \leq C_S(P') \leq S\) such that \(P'\) is \(\mathcal{F}\)-conjugate to \(P\), and such that there is \(1 \neq \alpha \in \text{Aut}_{\mathcal{F}}(QP')\) of order prime to \(p\) with \(\alpha|_{P'} = \text{Id}_{P'}\). Note that the set of \(\mathcal{F}\)-quasicentric subgroups of \(S\) is closed under \(\mathcal{F}\)-conjugation and overgroups. If \(\mathcal{F}\) is a saturated fusion system, then \(\mathcal{F}^q\) denotes the full subcategory whose objects are the \(\mathcal{F}\)-quasicentric subgroups of \(S\).

One way to extend the centric linking system of a \(p\)-local finite group \((S, \mathcal{F}, \mathcal{L})\) to a category containing other subgroups of \(S\) as objects is provided by [BLO2, §7]. There,
a (discrete) category $\mathcal{L}_{S,f}(X)$ is associated to any triple $(X, S, f)$, where $X$ is a space, $S$ is a $p$-group, and $f: BS \rightarrow X$ is a map. We recall this construction in the case where $f$ is the natural inclusion of $BS$ into $X = |\mathcal{L}|^\wedge_p$ ($f = |\theta_S|^\wedge$ as defined in the next paragraph). As we will see, $\mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)$ is then an extension of $\mathcal{L}$ containing all subgroups of $S$ as objects.

Let $(S, \mathcal{F}, \mathcal{L})$ be a $p$-local finite group, and let $\pi: \mathcal{L} \rightarrow \mathcal{F}^c$ be the projection functor. For each subgroup $P \leq S$, let $\mathcal{B}(P)$ be the category with one object $o_P$ and with $\text{End}_{\mathcal{B}(P)}(o_P) = P$, and identify $BP = |\mathcal{B}(P)|$. We let $\tilde{g}$ denote the morphism in $\mathcal{B}(P)$ corresponding to $g \in P$. Let

$$\theta_P: \mathcal{B}(P) \rightarrow \mathcal{L}$$

be the functor which sends $o_P$ to $P$, and sends a morphism $\tilde{g}$ (for $g \in P$) to $\delta_P(g) \in \text{Aut}_\mathcal{L}(P)$. This induces natural maps $|\theta_P|^\wedge_P: BP \rightarrow |\mathcal{L}|^\wedge_p$. For each $\varphi \in \text{Hom}_\mathcal{L}(P, Q)$, we can view $\pi(\varphi) \in \text{Hom}_\mathcal{F}(P, Q)$ as a functor $\mathcal{B}(P) \rightarrow \mathcal{B}(Q)$. Let

$$\eta_\varphi: \theta_P \rightarrow \theta_Q \circ \pi(\varphi)$$

be the natural transformation of functors given by

$$\theta_P(o_P) = P \xrightarrow{\varphi} Q = \theta_Q(\pi(\varphi)(o_P)).$$

This defines an explicit homotopy $|\eta_\varphi|: BP \times I \rightarrow |\mathcal{L}|^\wedge_p$ between $|\theta_P|^\wedge_P$ and $|\theta_Q|^\wedge_P \circ B\varphi$. If for each $\mathcal{F}$-centric subgroup $P \leq S$, we choose a morphism $\iota_P \in \text{Mor}_\mathcal{L}(P, S)$ which is sent to the inclusion of $P$ in $S$ by the projection functor to $\mathcal{F}$, we obtain a fixed collection of natural transformations $\eta_P$, and induced homotopies $|\eta_P|: BP \times I \rightarrow |\mathcal{L}|^\wedge_p$ from $|\theta_P|^\wedge_P$ to the restriction $|\theta_S|^\wedge_{BP}$.

Write $f = |\theta_S|^\wedge$ for short. $\mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)$ is defined as the category whose objects are the subgroups of $S$, and where morphisms are

$$\text{Mor}_{\mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)}(P, Q) = \{ (\varphi, [H]) \mid \varphi \in \text{Hom}(P, Q), [H] \in \text{Mor}_{\pi(\text{Map}(BP, |\mathcal{L}|^\wedge_p))}(f|_{BP}, f|_{BQ} \circ B\varphi) \}.$$  

Here, $\pi$ denotes the fundamental groupoid functor. A functor

$$\xi_\mathcal{L}: \mathcal{L} \rightarrow \mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)$$

is also defined as follows. On objects, $\xi_\mathcal{L}$ is the inclusion, and for each $\varphi \in \text{Mor}_\mathcal{L}(P, Q)$, $\xi_\mathcal{L}(\varphi) = (\pi_{P,Q}(\varphi), [H_\varphi])$, where $H_\varphi$ is the homotopy $BP \times I \rightarrow |\mathcal{L}|^\wedge_p$ defined by

$$H_\varphi(x, t) = \begin{cases} 
|\eta_P|(x, 1 - 3t) & 0 \leq t \leq \frac{1}{3} \\
|\eta_P|(x, 3t - 1) & \frac{1}{3} \leq t \leq \frac{2}{3} \\
|\eta_Q|(B\varphi(x), 3t - 2) & \frac{2}{3} \leq t \leq 1.
\end{cases}$$

By [BLO2, Proposition 7.3], $\xi_\mathcal{L}$ defines an equivalence of categories to the full subcategory $\mathcal{L}_{S,f}^c(|\mathcal{L}|^\wedge_p) \subseteq \mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)$ whose objects are the $\mathcal{F}$-centric subgroups of $|\mathcal{L}|^\wedge_p$. In this sense, we say that $\mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)$ is an extension of $\mathcal{L}$.

**Definition 3.2.** Let $(S, \mathcal{F}, \mathcal{L})$ be any p-local finite group. Let $\mathcal{L}^q \subseteq \mathcal{L}_{S,f}(|\mathcal{L}|^\wedge_p)$ be the full subcategory whose objects are the $\mathcal{F}$-quasicentric subgroups of $S$. Let

$$\pi: \mathcal{L}^q \rightarrow \mathcal{F}^q$$

be the functor which sends an $\mathcal{F}$-quasicentric subgroup to itself, and which sends a morphism $(\varphi, [H])$ to $\varphi$. For each object $P$ in $\mathcal{L}^q$, define the distinguished monomorphism

$$\delta_P: PC_S(P) \rightarrow \text{Aut}_{\mathcal{L}^q}(P)$$

as
by sending \( g \in P \cdot CS(P) \) to \((c_g,[H_g])\), where \( c_g \) is conjugation by \( g \) restricted to \( P \) and \( H_g \) is the homotopy \( BP \times I \xrightarrow{\eta g} BS \xrightarrow{f} \mathcal{L}_p^\wedge \) induced by the natural transformation \( \text{Id} \xrightarrow{\eta g} c_g \) which sends the unique object of \( B(P) \) to the morphism \( \hat{g} \) of \( B(S) \).

We call \( \mathcal{L}^q \) the associated quasicentric linking system to the \( p \)-local finite group \((S, \mathcal{F}, \mathcal{L})\). Note that the functor \( \xi_\mathcal{L} \) factors through \( \mathcal{L} \longrightarrow \mathcal{L}^q \), also denoted \( \xi_\mathcal{L} \). For any \( \mathcal{F} \)-centric subgroup \( P \leq S \) and any \( g \in P \), \([H_{\delta_P(g)}] = [H_g]\), where \( \delta_P \colon P \longrightarrow \text{Aut}_{\mathcal{L}_q}(P) \) is the distinguished monomorphism for the centric linking system \( \mathcal{L} \), and \( H_\hat{g} \) is the homotopy defined above. Hence \( \xi_\mathcal{L} \) is compatible with the projection functors of \( \mathcal{L} \) and \( \mathcal{L}^q \) to the fusion system \( \mathcal{F} \), and with the distinguished homomorphisms. In this way, we can think of \( \mathcal{L} \) as a subcategory of \( \mathcal{L}^q \) (with \( \xi_\mathcal{L} \) as inclusion functor), and regard \( \mathcal{L}^q \) as an extension of the centric linking system \( \mathcal{L} \).

There is also a homotopy theoretic characterization of \( \mathcal{F} \)-quasicentric subgroups. If we define a map \( f \colon X \to Y \) to be quasicentric if the homotopy fibre of the map \( f_0 \colon \text{Map}(X,X)_{\text{id}_X} \longrightarrow \text{Map}(X,Y) \) is homotopically discrete, then it turns out that \( P \leq S \) is \( \mathcal{F} \)-quasicentric in \((S, \mathcal{F}, \mathcal{L})\) if and only if the natural map \( f|_{BP} \colon BP \longrightarrow |\mathcal{L}_p^\wedge| \) is quasicentric.

**Proposition 3.3.** For any \( p \)-local finite group \((S, \mathcal{F}, \mathcal{L})\) and any \( P \leq S \), the following are equivalent:

(a) \( P \) is \( \mathcal{F} \)-quasicentric.

(b) There is a fully centralized subgroup \( P' \leq S \) which is \( \mathcal{F} \)-conjugate to \( P \) and such that \( \text{Map}(BP,|\mathcal{L}_p^\wedge|)_{f|_{BP}} \simeq \text{Map}(BP',|\mathcal{L}_p^\wedge|_{f|_{BP'}}) \simeq BS(P') \).

(c) The homotopy fibre of the map \( \text{Map}(BP,BP)_{\text{id}_{BP}} \longrightarrow \text{Map}(BP,|\mathcal{L}_p^\wedge|)_{f|_{BP}} \) is homotopically discrete.

(d) \( \text{Map}(BP,|\mathcal{L}_p^\wedge|)_{f|_{BP}} \) is an Eilenberg-MacLane space \( K(\pi,1) \).

**Proof.** ((a)\( \Rightarrow \)(b)) follows by definition of \( \mathcal{F} \)-quasicentric and [BLO2, Theorem 6.3].

((b)\( \Rightarrow \)(c)) and ((c)\( \Rightarrow \)(d)) follow from the long exact sequence of homotopy groups of the relevant fibration because \( \text{Map}(BP,BP)_{\text{id}_{BP}} \simeq BZ(P) \).

Finally we prove that ((d)\( \Rightarrow \)(a)). Let \( P' \) be a fully centralized subgroup of \( S \) which is \( \mathcal{F} \)-conjugate to \( P \). According to [BLO2, Theorem 6.3], we have that \( |C_\mathcal{L}(P')|_{p^\infty} \simeq \text{Map}(BP',|\mathcal{L}_p^\wedge|_{f|_{BP'}}) \simeq \text{Map}(BP,|\mathcal{L}_p^\wedge|_{f|_{BP}}) \simeq K(\pi,1) \). In particular \( \pi \cong \pi_1(|C_\mathcal{L}(P')|_{p^\infty}) \) is a finite \( p \)-group, and then the fusion system \( C_\mathcal{F}(P') \) coincides with the fusion system of \( \pi \) (see [BLO2, Theorem 7.3]). \( \square \)

From the definition, and the description of mapping spaces in [BLO2, Theorem 4.6], we see easily that associated quasicentric linking systems satisfy the same properties as were used to define associated centric linking systems to a saturated fusion system.

**Proposition 3.4.** Let \((S, \mathcal{F}, \mathcal{L})\) be any \( p \)-local finite group, and let \( \mathcal{L}^q \) be the associated quasicentric linking system. This satisfies the following conditions.

(A) \( \pi \) is the identity on objects and surjective on morphisms. For each pair of objects \( P, Q \in \mathcal{L}^q \) such that \( P \) is fully centralized, \( CS(P) \) acts freely on \( \text{Mor}_{\mathcal{L}_q}(P,Q) \) by composition (upon identifying \( CS(P) \) with \( \delta_P(\text{Mor}_{\mathcal{L}_q}(P,Q)) \leq \text{Aut}_{\mathcal{L}_q}(P) \)), and \( \pi \) induces a bijection \( \text{Mor}_{\mathcal{L}_q}(P,Q)/CS(P) \xrightarrow{\cong} \text{Hom}_{\mathcal{F}}(P,Q) \).
(B) For each \( \mathcal{F} \)-quasicentric subgroup \( P \leq S \) and each \( g \in P \), \( \pi \) sends \( \delta_P(g) \in \text{Aut}_{\mathcal{L}}(P) \) to \( c_g \in \text{Aut}_\mathcal{F}(P) \).

(C) For each \( f \in \text{Mor}_{\mathcal{C}}(P,Q) \) and each \( g \in P \), the following square commutes in \( \mathcal{L}^4 \):

\[
\begin{array}{ccc}
P & \xrightarrow{f} & Q \\
\downarrow{\delta_P(g)} & & \downarrow{\delta_Q(\pi(f)(g))} \\
P & \xrightarrow{f} & Q.
\end{array}
\]

Proof. The proof follows the lines of the proof of Theorem 7.5 in [BLO2]. \( \square \)

We are now ready to state the main result of this section:

**Theorem 3.5.** Let \((S, \mathcal{F}, \mathcal{L})\) be a \( p \)-local finite group and let \( \mathcal{L}^4 \) be the associated quasicentric linking system. Let \( \mathcal{L}' \subseteq \mathcal{L}^4 \) be any full subcategory which contains all \( \mathcal{F} \)-radical \( \mathcal{F} \)-centric subgroups of \( S \). Then the inclusions of \( \mathcal{L}' \) and \( \mathcal{L} \) in \( \mathcal{L}^4 \) induce homotopy equivalences \( |\mathcal{L}'| \simeq |\mathcal{L}^4| \simeq |\mathcal{L}| \).

Theorem 3.5 is an immediate consequence of Proposition 3.11 below. The rest of the section is directed towards the proof of that proposition. We first prove some lemmas that will provide us with a better understanding of morphism sets in \( \mathcal{L}^4 \).

**Lemma 3.6.** Fix a \( p \)-local finite group \((S, \mathcal{F}, \mathcal{L})\), and let \( \pi: \mathcal{L}^4 \longrightarrow \mathcal{F}^4 \) be the projection. Fix \( \mathcal{F} \)-quasicentric subgroups \( P,Q,R \) in \( S \). Let \( \varphi \in \text{Mor}_{\mathcal{C}}(P,R) \) and \( \psi \in \text{Mor}_{\mathcal{C}}(Q,R) \) be any pair of morphisms such that \( \text{Im}(\pi(\varphi)) \leq \text{Im}(\pi(\psi)) \). Then there is a unique morphism \( \chi \in \text{Mor}_{\mathcal{C}}(P,Q) \) such that \( \varphi = \psi \circ \chi \).

Proof. By definition of a fusion system, there is a unique morphism \( \overline{\chi} \in \text{Hom}_\mathcal{F}(P,Q) \) such that \( \pi(\varphi) = \pi(\psi) \circ \overline{\chi} \). Let \( \chi' \in \text{Mor}_{\mathcal{C}}(P,Q) \) be any morphism such that \( \pi(\chi') = \overline{\chi} \). Choose a fully centralized group \( P' \) in the \( \mathcal{F} \)-conjugacy class of \( P \) and a particular \( \alpha \in \text{Iso}_{\mathcal{C}}(P',P) \). Then by (A), there is a unique element \( g \in C_S(P') \) such that \( \varphi \circ \alpha = \psi \circ \chi' \circ \alpha \circ \delta_P(g) \), and we can define \( \chi = \chi' \circ \alpha \circ \delta_P(g) \circ \alpha^{-1} \).

If \( \chi_1 \in \text{Mor}_{\mathcal{C}}(P,Q) \) is any other morphism such that \( \varphi = \psi \circ \chi_1 \), then \( \pi(\chi) = \pi(\chi_1) \), hence by (A) again, there is a unique element \( h \in C_S(P') \) such that \( \chi \circ \alpha = \chi_1 \circ \alpha \circ \delta_P(h) \); and since \( \psi \circ \chi_1 \circ \alpha = \psi \circ \chi \circ \alpha = \psi \circ \chi_1 \circ \alpha \circ \delta_P(h) \), and the action of \( C_S(P') \) on \( \text{Mor}_{\mathcal{C}}(P',Q) \) is free, we obtain \( h = 1 \) and then \( \chi = \chi_1 \). \( \square \)

**Lemma 3.7.** Fix a \( p \)-local finite group \((S, \mathcal{F}, \mathcal{L})\). Let \( \mathcal{L}^4 \) be the associated quasicentric linking system and let \( \pi: \mathcal{L}^4 \longrightarrow \mathcal{F}^4 \) be the projection. Fix a choice of an inclusion morphism \( \iota_P \in \text{Mor}_{\mathcal{C}}(P,S) \) for each \( \mathcal{F} \)-quasicentric subgroup \( P \leq S \) such that \( \pi(\iota_P) = \text{incl} \in \text{Hom}(P,S) \) and \( \iota_S = \text{Id}_S \). Then, there are unique injections

\[
\delta_{P,Q}: N_S(P,Q) \longrightarrow \text{Mor}_{\mathcal{C}}(P,Q),
\]

for all \( \mathcal{F} \)-quasicentric subgroups \( P,Q \leq S \), such that:

(a) \( \pi(\delta_{P,Q}(g)) = c_g \in \text{Hom}(P,Q) \), for all \( g \in N_S(P,Q) \),
(b) \( \delta_{P,S}(1) = \iota_P \) and \( \delta_{P}(g) = \delta_{P}(g) \), for all \( g \in P \cdot C_S(P) \),
(c) \( \delta_{Q,R}(h) \circ \delta_{P,Q}(g) = \delta_{P,R}(hg) \), for all \( g \in N_S(P,Q) \) and \( h \in N_S(Q,R) \).

Proof. This follows easily from Proposition 3.4 and Lemma 3.6 (see [BLO2, Proposition 1.11]). \( \square \)
For the rest of the section, whenever we are given a $p$-local finite group $\langle S, F, \mathcal{L}\rangle$, we assume that we have chosen morphisms $\iota_P \in \text{Mor}_\mathcal{L}(P, S)$, for each object $P$, such that $\pi(\iota_P)$ is the inclusion. Then for each $P \leq Q$ in $\mathcal{L}$, we let $\iota_P^Q \in \text{Mor}_\mathcal{L}(P, Q)$ be the unique morphism such that $\iota_P = \iota_Q \circ \iota_P^Q$ (Lemma 3.6). If $\varphi \in \text{Mor}_\mathcal{L}(P, Q)$, and $P' \leq P$ and $Q' \leq Q$ are quasicentric subgroups such that $\pi(\varphi)(P') \leq Q'$, then we write $\varphi|_{P'}^Q \in \text{Mor}_\mathcal{L}(P', Q')$ for the “restriction” of $\varphi$: the unique morphism $\circ \iota_P^Q \circ \varphi|_{P'} = \varphi \circ \iota_P^Q$ (Lemma 3.6 again). We also write $\varphi|_{P'} = \varphi|_P^{Q'}$ when the target group $Q'$ is clear from the context.

**Lemma 3.8.** Fix a saturated fusion system $F$ over a $p$-group $S$, and let $Q \leq S$ be an $F$-quasicentric subgroup. Let $P \leq S$ be such that $Q \lhd P$, and let $\varphi, \varphi' \in \text{Hom}_F(P, S)$ be such that $\varphi|_Q = \varphi'|_Q$. Then there is $x \in C_S(\varphi(Q))$ such that $\varphi' = c_x \circ \varphi$.

**Proof.** We first reduce this to the case where $Q$ is fully centralized and $\varphi'$ is the inclusion of $P$ in $S$. Upon replacing $P$ by $\varphi'(P)$ and $Q$ by $\varphi(Q) = \varphi'(Q)$, we can assume that $\varphi' = \text{incl}^Q_P$ and $\varphi|_Q = \text{Id}_Q$. By Lemma 2.3 (condition (IIA) holds), there is a fully normalized subgroup $Q'$ in the $F$-conjugacy class of $Q$, and a morphism $\beta: N_S(Q) \to N_S(Q')$ in $F$ which sends $Q$ to $Q'$. Now replace $P, Q$, and $\varphi$ by $\beta(P), Q'$, and $\beta \circ \varphi \circ \beta^{-1}$.

The idea of the proof is to show that for some $x \in C_S(Q)$, we can extend $\varphi \circ c_x$ to some $\overline{\varphi} \in \text{Hom}_F(P, S)$, for some $\overline{P} \geq P$, such that $\overline{\varphi}|_Q = \text{Id}_Q$, where $Q \leq \overline{Q} < \overline{P}$. The lemma then follows by downward induction on $|Q|$. Recall that the lemma holds when $Q$ is $F$-centric by [BLO2, Proposition A.8].

By definition of an $F$-quasicentric subgroup, $\varphi|_{C_P(Q)}$ is conjugation by some element $x \in C_S(Q)$. So after composing with $c_x$, we can assume that $\varphi|_{C_P(Q)} = \text{Id}_{C_P(Q)}$. We are thus done if $C_P(Q) \cdot Q \geq Q$ by taking $\overline{P} = P$ and $\overline{Q} = C_P(Q) \cdot Q$.

Assume now that $C_P(Q) \leq Q$. Set $K = \text{Aut}_P(Q)$. As in [BLO2, Appendix A], we write

$$N^F_S(Q) = \{x \in N_S(Q) \mid c_x \in K\},$$

and let $N^F_S(Q)$ be the fusion system over $N^F_S(Q)$ whose morphisms are defined (for $P, P' \leq N^F_S(Q)$) by

$$\text{Hom}_{N^F_S(Q)}(P, P') = \{\varphi \in \text{Hom}_F(P, P') \mid \psi|_P = \varphi, \psi|_Q \in K, \text{ some } \psi \in \text{Hom}_F(PQ, PQ')\}.$$

Then $P, \varphi(P)$, and $C_S(Q)$ are all contained in $N^F_S(Q)$. If $Q$ is not fully $K$-normalized in $F$, then there is some $\psi \in \text{Hom}_F(N^F_S(Q), S)$ such that $\psi(Q)$ is fully $\psi K \psi^{-1}$-normalized in $F$ (see [BLO2, Proposition A.2(b)]); and upon replacing all of these subgroups by their images under $\psi$, we are reduced to the case where $Q$ is fully $K$-normalized in $F$. The fusion system $N^F_S(Q)$ is saturated by [BLO2, Proposition A.6]; and upon replacing $F$ by $N^F_S(Q)$ we can assume that $S = N^F_S(Q) = P \cdot C_S(Q)$ and $F = N^F_S(Q)$. In particular, each $\alpha \in \text{Hom}_F(R, R')$ extends to a morphism in $\text{Hom}_F(RQ, R'Q)$ whose restriction to $Q$ is conjugation by some element of $P$.

Fix $\psi \in \text{Hom}_F(P, S)$ such that $\psi(P)$ is fully normalized in $F$. Since $\psi|_Q$ is conjugation by an element $g \in P$, we can replace $\psi$ by $\psi \circ c_g^{-1}$, and thus arrange that $\psi|_Q = \text{Id}$. If $\psi$ and $\psi \circ \varphi^{-1}$ are both conjugation by some element of $C_S(Q)$, then so is $\varphi$; so it suffices to prove the result under the assumption that $\varphi(P)$ is fully normalized in $F$.

Now, $(C_S(Q) \cdot Q)/Q$ is a nontrivial normal subgroup of $N_S(Q)/Q = S/Q$. So there is an element $x \in C_S(Q) \cdot Q$ such that $1 \neq xQ \in Z(S/Q)$. Then $x \in N_S(P)$, and acts
via the identity on $Q$ and on $P/Q$. Thus
\[ c_x \in \ker \left[ \text{Aut}_F(P) \rightarrow \text{Aut}_F(Q) \times \text{Aut}(P/Q) \right], \]
a normal $p$-subgroup of $\text{Aut}_F(P)$ (see [Go, Corollary 5.3.3]). Also, $\text{Aut}_S(\varphi(P)) \in \text{Syl}_p(\text{Aut}_F(\varphi(P)))$ since $\varphi(P)$ is fully normalized. In particular, $\varphi c_x \varphi^{-1} \in \text{Aut}_S(\varphi(P))$ (after replacing $\varphi$ by $\varphi \circ \xi$ where $\xi \in \text{Aut}_F(\varphi(P))$ if necessary). Thus, $x \in N_\varphi$ and $Q \trianglelefteq N_\varphi$. By (II), $\varphi$ extends to $\bar{\varphi} \in \text{Hom}_F(N_\varphi, S)$. Now set $\bar{P} = N_\varphi \cap N_S(Q) = N_\varphi$ and $\bar{Q} = C_{\bar{P}}(Q) \cdot Q$.

By construction, $x \in \bar{Q} \setminus Q$. Since $Q$ is $F$-quasicentric, $\bar{\varphi}|_{\bar{C}_{\bar{P}}(Q)}$ is conjugation by some element $g \in C_S(Q)$. So we can replace $\bar{\varphi}$ by $\bar{\varphi} \circ (c_g)^{-1}$, and thus arrange that $\bar{\varphi}|_{\bar{Q}} = \text{Id}_{\bar{Q}}$. Since $\bar{Q} \supseteq Q$ and $\bar{Q} \triangleleft \bar{P}$, this finishes the induction step. \qed

The next lemma can be thought of as a “lifting” of the last one to quasicentric linking systems. It says that all inclusions in $L^q$ are epimorphisms in the categorical sense.

**Lemma 3.9.** Fix a $p$-local finite group $(S, F, L)$, and let $L^q$ be the associated quasicentric linking system. Assume $Q \leq P \leq S$ and $R \leq S$ are $F$-quasicentric, and let $\varphi, \varphi' \in \text{Mor}_{L^q}(P, R)$ be two morphisms such that $\varphi \circ t^P_Q = \varphi' \circ t^P_Q$. Then $\varphi = \varphi'$.

**Proof.** Since there is always a subnormal series $Q = Q_0 \triangleleft Q_1 \triangleleft \cdots \triangleleft Q_k = P$, it suffices to prove the lemma when $Q$ is normal in $P$. So we assume this from now on.

It will be convenient, throughout the proof, to write $\bar{\alpha} = \pi(\alpha) \in \text{Mor}(F)$ for any $\alpha \in \text{Mor}(L^q)$. By Lemma 3.6, $\varphi = \varphi'$ if and only if $t^R_Q \circ \varphi = t^R_Q \circ \varphi' \in \text{Mor}_{L^q}(P, S)$, and similarly replacing $\varphi$ (resp. $\varphi'$) by $\varphi \circ t^P_Q$ (resp. $\varphi' \circ t^P_Q$). We can thus replace $R$ by any other subgroup of $S$ which contains the images of $\bar{\varphi}$ and $\bar{\varphi}'$, and in particular assume that $R \leq N_S(\bar{\varphi}(Q))$.

The proof itself will be divided in two steps: the first dealing with a restricted case, and the second reducing the general case to that in Step 1.

**Step 1:** Assume first that $Q = \bar{\varphi}(Q)$ and is fully normalized, and that $P$ is fully centralized. Set $\varphi_0 = \varphi \circ t^P_Q = \varphi' \circ t^P_Q$. By condition (II) in Definition 1.3 (and since $Q = \bar{\varphi}_0(Q)$ is fully centralized), there is $\bar{\psi} \in \text{Hom}_F(P \cdot C_S(Q), S)$ such that $\bar{\psi}|_{\bar{Q}} = \bar{\varphi}_0$. Choose any $\varphi'' \in \text{Mor}_{L^q}(P, S)$ such that $\bar{\varphi}'' = \bar{\psi}|_{\bar{P}}$. Thus $\varphi''|_{\bar{Q}} = \bar{\varphi}_0$, so there is a unique element $a \in C_S(Q)$ such that
\[ \varphi'' \circ t^P_Q = \varphi_0 \circ \delta(a). \]

By Lemma 3.8, there is some $x \in C_S(\bar{\varphi}(Q))$ such that $c_x \circ \bar{\varphi} \circ t^S_Q = \varphi''$. Since $P$ is fully centralized, by Proposition 3.4(A), there is $y \in C_S(P)$ such that
\[ \delta(x) \circ \varphi = \varphi'' \circ \delta(y) = \delta(\bar{\psi}(y)) \circ \varphi''. \]

It follows that $\varphi'' = \delta(z) \circ \varphi$, where $z = \bar{\psi}(y)^{-1} \cdot x \in C_S(\bar{\varphi}_0(Q))$. Hence
\[ \delta(z) \circ \varphi_0 = \varphi'' \circ t^P_Q = \varphi \circ t^P_Q \circ \delta(a) = \delta(\bar{\psi}(a)) \circ \varphi_0. \]

Since $\varphi_0 = t^S_Q \circ \omega$ for some $\omega \in \text{Aut}_{L^q}(Q)$, upon composing with $\omega^{-1}$, this shows that $\delta_{Q,S}(\bar{\psi}(a)) = \delta_{Q,S}(z)$, and hence that $z = \bar{\psi}(a)$.

After making a similar argument involving $\varphi'$, we now have
\[ \delta(\bar{\psi}(a)) \circ \varphi = \varphi'' = \delta(\bar{\psi}(a)) \circ \varphi', \]
and this shows that $\varphi = \varphi'$. 

Step 2: (General case.) We first reduce the problem to the case in which $P$ is fully centralized. We choose an isomorphism $\xi \in \text{Mor}_{\mathcal{L}}(P, P')$ such that $\hat{\xi}(P) = P'$ is fully centralized. Upon replacing $P$ by $P'$, $\varphi$ by $\varphi \circ \xi^{-1}$, and $\varphi'$ by $\varphi' \circ \xi^{-1}$ we are now reduced to the case where $P$ is fully centralized in $\mathcal{F}$.

Set $Q' = \hat{\varphi}(Q) = \hat{\varphi}'(Q)$ for short; we now reduce the problem to the case in which $Q = Q'$ and is fully centralized. Let $Q''$ be any fully normalized subgroup in the $\mathcal{F}$-conjugacy class of $Q$ (and of $Q'$). By Lemma 2.3 (condition (IIB) holds), there are morphisms

$$\beta \in \text{Mor}_{\mathcal{L}}(N_S(Q), N_S(Q'')) \quad \text{and} \quad \beta' \in \text{Mor}_{\mathcal{L}}(N_S(Q'), N_S(Q''))$$

such that $\hat{\beta}(Q) = \hat{\beta}'(Q') = Q''$. Set $P'' = \hat{\beta}(P)$, and let $\beta_0 \in \text{Iso}_{\mathcal{L}}(P, P'')$ be the restriction of $\beta$ (i.e., by Lemma 3.6 the unique morphism such that $\iota_{P''}^{N_S(Q'')} \circ \beta_0 = \beta \circ \iota_P^{N_S(Q)}$).

Set

$$\psi = \beta' \circ \iota_R^{N_S(Q''')} \circ \varphi \circ \beta_0^{-1}, \quad \psi' = \beta' \circ \iota_R^{N_S(Q'')} \circ \varphi' \circ \beta_0^{-1} \in \text{Mor}_{\mathcal{L}}(P'', N_S(Q'')).$$

Then $\psi = \psi'$ if and only if $\varphi = \varphi'$, and $\psi \circ \iota_{Q''}^P = \psi' \circ \iota_{Q''}^P$ if and only if $\varphi \circ \iota_Q^P = \varphi' \circ \iota_Q^P$. Note that $P''$ is $\mathcal{F}$-conjugated to $P$ and the following inequality holds:

$$|C_S(P)| = |C_{N_S(Q)}(P)| \leq |C_{N_S(Q'')}| = |C_S(P'')|.$$

Since $P$ is fully centralized, it follows that $|C_S(P)| = |C_S(P'')|$ and $P''$ is also fully centralized.

Thus, upon replacing $(Q, P, R)$ by $(Q'', P'', N_S(Q''))$, $\varphi$ by $\psi$, and $\varphi'$ by $\psi'$, we are reduced to the case where $Q = \varphi(Q)$ is fully normalized and $P$ is fully centralized. \qed

An immediate consequence of Lemmas 3.6 and 3.9 is:

**Corollary 3.10.** Fix a $p$-local finite group $(S, \mathcal{F}, \mathcal{L})$, and let $\mathcal{L}^q$ be the associated quasicentric linking system. Then all morphisms in $\mathcal{L}^q$ are monomorphisms and epimorphisms in the categorical sense.

*Proof.* By the uniqueness in Lemma 3.6, $\psi \circ \chi = \psi \circ \chi'$ in $\mathcal{L}^q$ implies $\chi = \chi'$. Hence all morphisms in $\mathcal{L}^q$ are monomorphisms.

Since each morphism in $\mathcal{L}^q$ is the composite of an isomorphism followed by an inclusion, it suffices to prove that inclusions $\iota_Q^P$ are epimorphisms, and it clearly suffices to do this when $Q \leq P$. So assume $P' \leq S$ and $\varphi, \varphi' \in \text{Mor}_{\mathcal{L}}(P, R)$ are such that $\varphi \circ \iota_Q^P = \varphi' \circ \iota_Q^P$. Then $\iota_{P'}^S \circ \varphi = \iota_{P'}^S \circ \varphi'$ by Lemma 3.9, and so $\varphi = \varphi'$ by Lemma 3.6. \qed

We are now ready to prove the following proposition, of which Theorem 3.5 is an immediate consequence.

**Proposition 3.11.** Let $(S, \mathcal{F}, \mathcal{L})$ be a $p$-local finite group, and let $\mathcal{L}^q$ be the quasicentric linking system associated to $\mathcal{L}$. Let $\mathcal{L}_0 \subseteq \mathcal{L}^q$ be any full subcategory such that $\text{Ob}(\mathcal{L}_0)$ is closed under $\mathcal{F}$-conjugacy. Let $P \in \text{Ob}(\mathcal{L}^q)$ be maximal among those $\mathcal{F}$-quasicentric subgroups not in $\mathcal{L}_0$, and let $\mathcal{L}_1 \subseteq \mathcal{L}^q$ be the full subcategory whose objects are the objects in $\mathcal{L}_0$ together with all subgroups $\mathcal{F}$-conjugate to $P$. Assume furthermore that $P$ is not $\mathcal{F}$-centric or not $\mathcal{F}$-radical. Then the inclusion of nerves $|\mathcal{L}_0| \subseteq |\mathcal{L}_1|$ is a homotopy equivalence.

*Proof.* Throughout the following proof, when working in any linking system, we assume that inclusion morphisms $\iota_P^Q$ have been chosen as in Lemma 3.7. By “extensions” and “restrictions” of morphisms we mean with respect to these inclusions. Also, for
For any morphism \( r \), we write \( \text{Im}(\varphi) = \text{Im}(\pi(\varphi)) \leq Q' \) and \( \varphi(R) = \pi(\varphi)(R) \leq Q' \) if \( R \leq Q \).

We must show that the inclusion functor \( i : \mathcal{L}_0 \to \mathcal{L}_1 \) induces a homotopy equivalence \( |\mathcal{L}_0| \simeq |\mathcal{L}_1| \). By Theorem A in [Qu2], it will be enough to prove that the undercategory \( Q \downarrow i \) is contractible (i.e., \( |Q \downarrow i| \simeq * \)) for each \( Q \) in \( \mathcal{L}_1 \). This is clear when \( Q \) is not isomorphic to \( P \) (since \( Q \downarrow i \) has initial object \((Q, \text{Id})\) in that case), so it suffices to consider the case \( Q = P \). Since \( P \) was arbitrarily chosen in its isomorphism class, we can also assume that \( P \) is fully normalized.

Let
\[
\iota_N : \mathcal{L}_0 \cap N_{\mathcal{L}_0}(P) \longrightarrow \mathcal{L}_1 \cap N_{\mathcal{L}_0}(P)
\]
be the restriction of \( \iota \). Consider the functor \( i : P \downarrow \iota_N \to P \downarrow \iota \) induced by the inclusions \( \mathcal{L}_i \cap N_{\mathcal{L}_i}(P) \to \mathcal{L}_i \) for \( i = 0, 1 \). We will first show that \( |P \downarrow \iota| \simeq |P \downarrow \iota_N| \) and then that \( |P \downarrow \iota_N| \simeq * \).

To prove the first statement, we construct a retraction functor \( r : P \downarrow \iota \to P \downarrow \iota_N \) such that \( r \circ i = \text{Id}_{P \downarrow \iota_N} \), together with a natural transformation \( (i \circ r) \cong \text{Id}_{P \downarrow \iota} \). By Lemma 2.3 (condition (IB)), for each \( P' \leq S \) which is \( \mathcal{F} \)-conjugate to \( P \), there is a morphism in \( \mathcal{F} \) from \( N_S(P') \) to \( N_S(P) \) which sends \( P' \) isomorphically to \( P \). Hence upon lifting this to the linking system, we can choose a morphism
\[ \Phi_{P'} \in \text{Mor}_{\mathcal{L}_0}(N_S(P'), N_S(P)) \]
for each such \( P' \) which restricts to an isomorphism from \( P' \) to \( P \). In particular, we set \( \Phi_P = \text{Id}_{N_S(P)} \).

For each nonisomorphism \( \varphi \in \text{Mor}_{\mathcal{L}_0}(P, Q) \), set \( \widehat{\varphi} = \Phi_{\varphi(P)}(N_Q(\varphi(P))) \geq P \). We can factor \( \varphi \) as \( \varphi = \eta(\varphi) \circ r(\varphi) \), where
\[ r(\varphi) = i_P^Q \circ (\Phi_{\varphi(P)}|_{\varphi(P)}) \circ \varphi \in \text{Mor}_{\mathcal{L}_0}(P, \widehat{\varphi}(\varphi)) \]
and
\[ \eta(\varphi) = i_Q^Q \circ (\Phi_{\varphi(P)}|_{\widehat{\varphi}(\varphi)})^{-1} \in \text{Mor}_{\mathcal{L}_0}(\widehat{\varphi}(\varphi), Q), \]
where \( \widehat{Q} = N_Q(\varphi(P)) \). We define the functor \( r : P \downarrow \iota \to P \downarrow \iota_N \) on objects by setting
\[ r(P \stackrel{\varphi}{\longrightarrow} Q) = (P \stackrel{r(\varphi)}{\longrightarrow} \widehat{\varphi}(\varphi) \stackrel{\eta(\varphi)}{\longrightarrow} Q). \]
For any morphism \( \beta \in \text{Mor}_{P \downarrow \mathcal{L}_0}((Q, \varphi), (Q', \varphi')) \); i.e., for any commutative square of the form
\[
\begin{array}{ccc}
P & \longrightarrow & Q \\
\downarrow \text{Id} & & \downarrow \beta \\
P & \varphi' \longrightarrow & Q',
\end{array}
\]
we claim there is a unique morphism \( \widehat{\varphi}(\beta) \) such that the two squares in the following diagram commute:
\[
\begin{array}{ccc}
P & \longrightarrow & \widehat{\varphi}(\varphi) \\
\downarrow \text{Id} & & \downarrow \beta \\
P & \overset{r(\varphi)}{\longrightarrow} & \widehat{\varphi}(\varphi) \overset{\eta(\varphi)}{\longrightarrow} Q \\
\end{array}
\]
To see this, note that by commutativity of the square (2), \( \beta \) sends \( N_Q(\varphi(P)) \) into \( N_{Q'}(\varphi'(P)) \). Hence upon defining
\[ \widehat{\varphi}(\beta) \overset{\text{def}}{=} \Phi_{\varphi'(P)} \circ \beta \circ \Phi_{\varphi(P)}^{-1}, \]
where the three morphisms are replaced by appropriate restrictions, we get \( \hat{\tau}(\beta) \) such that the right square in (3) commutes. Since the combination of the two squares commutes by assumption, we obtain that \( \eta(\varphi') \circ \hat{\tau}(\beta) \circ r(\varphi) = \eta(\varphi') \circ r(\varphi') \), and therefore \( \hat{\tau}(\beta) \circ r(\varphi) = r(\varphi') \) by Lemma 3.6. By the uniqueness of \( \hat{\tau}(\beta) \), it follows that this construction defines a functor, as well as a natural transformation \( i \circ r \longrightarrow \eta \to \text{Id}_{P \downarrow \mu_i} \).

Since \( r \circ i = \text{Id}_{P \downarrow \mu_i} \), this finishes the proof that \( |P \downarrow \mu| \simeq |P \downarrow \mu_N| \).

It remains to prove that \( |P \downarrow \mu_N| \simeq \ast \). Set

\[
\hat{P} = \{ x \in N_S(P) \mid c_x \in O_p(\text{Aut}_F(P)) \}.
\]

Note that \( \hat{P} \geq P \cdot C_S(P) \), and hence \( \hat{P} \geq P \) if \( P \) is not centric. Moreover, \( \hat{P} \geq P \) if \( P \) is not radical, and thus \( \hat{P} \in \mathcal{L}_0 \) in both cases covered by the hypotheses of the proposition. Since \( P \) is normal in \( \hat{P} \), this last is an object in \( \mathcal{L}_0 \cap N_{\mathcal{L}_0}(P) \).

Recall that \( \iota_N : \mathcal{L}_0 \cap N_{\mathcal{L}_0}(P) \to \mathcal{L}_1 \cap N_{\mathcal{L}_0}(P) \) denotes the inclusion. Let \( i \) be the functor \( i : \hat{P} \downarrow \mu_i \to P \downarrow \mu_i \) which is induced by precomposing with the inclusion \( \iota_P^P \in \text{Mor}_{\mathcal{L}_0}(P, \hat{P}) \). We show that \( i \) induces a homotopy equivalence \( |P \downarrow \mu_N| \simeq |\hat{P} \downarrow \mu_N| \), by defining a functor \( r : P \downarrow \mu_N \to \hat{P} \downarrow \mu_N \) such that \( r \circ i = \text{Id}_{\hat{P} \downarrow \mu_i} \), and such that \( i \circ r \simeq \text{Id}_{P \downarrow \mu_N} \) (such that there is a natural transformation of functors from the identity to \( i \circ r \)). Then \( |P \downarrow \mu_N| \simeq |\hat{P} \downarrow \mu_N| \), and the last space is contractible since \( \hat{P} \in \mathcal{L}_0 \cap N_{\mathcal{L}_0}(P) \). This will finish the proof.

Fix subgroups \( Q, Q' \leq N_S(P) \) containing \( P \), and a morphism \( \varphi \in \text{Mor}_{N_{\mathcal{L}_0}(P)}(Q, Q') \). Set \( \alpha = \pi(\varphi)|_P \in \text{Aut}_F(P) \) for short. Since \( P \) is fully normalized, \( \text{Aut}_S(P) \in \text{Syl}_p(\text{Aut}_F(P)) \), and hence \( O_p(\text{Aut}_F(P)) \leq \text{Aut}_S(P) \). It follows that

\[
N_\alpha \overset{\text{def}}{=} \{ x \in N_S(P) \mid \alpha c_x \alpha^{-1} \in \text{Aut}_S(P) \} \geq \hat{P};
\]

and \( N_\alpha \geq Q \) since \( \alpha \) extends to \( \pi(\varphi) \in \text{Hom}_F(Q, Q') \). Thus, since \( P \) is fully centralized, \( \alpha \) extends to some \( \varphi' \in \text{Hom}_F(Q \hat{P}, Q' \hat{P}) \) by condition (II) in Definition 1.3. After possibly composing this extension with \( \delta_{Q \hat{P}}(x) \) for some element \( x \in C_S(P) \leq Q \hat{P} \), we get a lifting \( \hat{\varphi} \in \text{Mor}_{\mathcal{L}_0}(Q \hat{P}, Q' \hat{P}) \) such that the following diagram commutes in \( \mathcal{L}_0' \):

\[
\begin{array}{ccc}
P & \overset{i_P^Q}{\longrightarrow} & Q \\
\downarrow i_P^{Q \hat{P}} & & \downarrow i_P^{Q' \hat{P}} \\
Q \hat{P} & \overset{\hat{\varphi}}{\longrightarrow} & Q' \hat{P}.
\end{array}
\]

Hence by Lemma 3.9, \( \hat{\varphi} \circ i_P^{Q \hat{P}} = i_P^{Q' \hat{P}} \circ \varphi \). This lifting is unique by Corollary 3.10; and it lies in \( \mathcal{L}_0 \cap N_{\mathcal{L}_0}(P) \), or in \( \mathcal{L}_1 \cap N_{\mathcal{L}_0}(P) \) if \( Q = P \).

The functor \( r \) is defined on objects by setting

\[
r(P \overset{\varphi}{\longrightarrow} Q) = (\hat{P} \overset{\varphi}{\longrightarrow} Q \hat{P}).
\]

If \( \beta : Q \to Q' \) is a morphism such that \( \beta \circ \varphi = \varphi' \), then we define \( r(\beta) = \hat{\beta} \). Because of the uniqueness of the extension \( \hat{\beta} \), this construction defines a functor. Moreover, \( r \circ i = \text{Id}_{\hat{P} \downarrow \mu_i} \), and \( i \circ r \simeq \text{Id}_{P \downarrow \mu_N} \), where the homotopy is induced by the natural transformation given by the inclusions \( i_P^{Q \hat{P}} \). \( \square \)
4. Constrained fusion systems

We now look at a class of saturated fusion systems which have very simple, regular behavior: the **constrained** fusion systems. The main results here say that constrained fusion systems are always realized as fusion systems of finite groups in a predictable way, and have unique associated centric linking systems.

Let $\mathcal{F}$ be an arbitrary saturated fusion system over a $p$-group $S$. Recall (Definition 1.5) that a subgroup $Q \triangleleft S$ is **normal in** $\mathcal{F}$ if each $\alpha \in \text{Hom}_\mathcal{F}(P,P')$ extends to a morphism $\overline{\alpha} \in \text{Hom}_\mathcal{F}(PQ,P'Q)$ which sends $Q$ to itself. If $Q$ and $Q'$ are both normal in $\mathcal{F}$, then clearly $QQ'$ is normal in $\mathcal{F}$. Hence, there is a unique maximal normal $p$-subgroup in $\mathcal{F}$, which we denote $O_p(\mathcal{F})$ by analogy with the subgroup $O_p(G)$ of a finite group $G$. By Proposition 1.6, $O_p(\mathcal{F})$ is contained in the intersection of all $\mathcal{F}$-radical subgroups of $S$. We are interested in the case when $O_p(\mathcal{F})$ is itself $\mathcal{F}$-centric, or equivalently, when there is a subgroup $P \triangleleft S$ which is both normal and centric in $\mathcal{F}$.

**Definition 4.1.** A saturated fusion system $\mathcal{F}$ over a $p$-group $S$ is **constrained** if there is some $Q \triangleleft S$ which is $\mathcal{F}$-centric and normal in $\mathcal{F}$.

When $G$ is a finite $p'$-reduced group, then $G$ is said to be $p$-**constrained** if there exists some normal $p$-subgroup $P \triangleleft G$ which is centric in $G$ (i.e., $C_G(P) \leq P$). (More generally, an arbitrary finite group $G$ is $p$-constrained if its $p'$-reduction $G/O_{p'}(G)$ is $p$-constrained.) Our aim is to show that any constrained fusion system is the fusion system of a unique $p'$-reduced $p$-constrained group $G$. This will be done by first showing that each constrained fusion system has a unique associated centric linking system $L$, and then choosing $G$ to be a certain automorphism group in $L$.

We first show that for any constrained fusion system, the obstruction groups to the existence and uniqueness of an associated centric linking system vanish. For any saturated fusion system $\mathcal{F}$, let $Z_\mathcal{F}$ denote the functor on $O(\mathcal{F}^c)$ defined by setting $Z_\mathcal{F}(P) = Z(P)$ for all $\mathcal{F}$-centric $P \leq S$. (See [BLO2, §3] for details.)

**Proposition 4.2.** Let $\mathcal{F}$ be any constrained saturated fusion system over a $p$-group $S$. Then

$$\lim_{O(\mathcal{F}^c)}^i(Z_\mathcal{F}) = 0 \quad \text{for all } i > 0.$$  

In particular, there is a centric linking system $L$ associated to $\mathcal{F}$ which is unique up to isomorphism.

**Proof.** Fix $Q \triangleleft S$ which is $\mathcal{F}$-centric and normal in $\mathcal{F}$. Let $P_1, P_2, \ldots, P_m$ be $\mathcal{F}$-conjugacy class representatives for all $\mathcal{F}$-centric subgroups $P \leq S$ such that $P \not\triangleright Q$, arranged such that $|P_i| \leq |P_{i+1}|$ for each $i$. For $i = 0, 1, \ldots, m$, let $Z_i \subseteq Z_\mathcal{F}$ be the subfunctor

$$Z_i(P) = \begin{cases} 
Z(P) & \text{if } P \text{ is conjugate to } P_j \text{ for some } j > i \\
0 & \text{otherwise.}
\end{cases}$$

This gives a sequence of subfunctors $Z_\mathcal{F} \supseteq Z_0 \supseteq Z_1 \supseteq \cdots \supseteq Z_m = 0$, where for each $i = 1, \ldots, m$, $Z_{i-1}/Z_i$ vanishes except on subgroups $\mathcal{F}$-conjugate to $P_i$. Hence by [BLO2, Proposition 3.2],

$$\lim_{O(\mathcal{F}^c)}^i(Z_{i-1}/Z_i) \cong \Lambda^*(\text{Out}_\mathcal{F}(P_i); Z(P_i)).$$
Furthermore, since $P_i \not\leq Q$, $N_{P_i Q}(P_i)/P_i \cong \text{Out}_Q(P_i)$ is a nontrivial normal $p$-subgroup of $\text{Out}_F(P_i)$ (normal by the same argument as the one used in the proof of Proposition 1.6), and so $\Lambda^*(\text{Out}_F(P_i); Z(P_i)) = 0$ by [JMO, Proposition 6.1(iii)]. This proves that $\varprojlim^*(Z_i) = 0$ for all $i$, and in particular that $\varprojlim^*(Z_0) = 0$. Thus

$$\varprojlim_{\mathcal{O}(F)}^*(Z_F) \cong \varprojlim_{\mathcal{O}(F)}^*(Z_F/Z_0),$$

(1)

where $Z_F/Z_0$ is the quotient functor

$$(Z_F/Z_0)(P) = \begin{cases} Z(P) = Z(Q)^P & \text{if } P \geq Q \\ 0 & \text{if } P \not\leq Q. \end{cases}$$

(2)

Now set $\Gamma = \text{Out}_F(Q)$ and $S_0 = \text{Out}_S(Q) \cong S/Q$. Thus $S_0 \in \text{Syl}_p(\Gamma)$. Set $M = Z(Q)$, regarded as a $Z(p)[\Gamma]$-module. Let $H^0M$ be the fixed-point functor on $\mathcal{O}_{S_0}(\Gamma)$ defined by $H^0M(P) = M^P$. Then $H^0M$ is acyclic by [JM, Proposition 5.14] (shown more explicitly in [JMO, Proposition 5.2]). So by (1), we will be done upon showing that

$$\varprojlim_{\mathcal{O}(F)}^*(Z_F/Z_0) \cong \varprojlim_{\mathcal{O}(F)}^*(H^0M).$$

(3)

Since $Q$ is normal and centric in $F$, it is easy to check that $\mathcal{O}_{S_0}(\Gamma)$ is isomorphic to the full subcategory of $\mathcal{O}(\mathcal{F})$ with objects the subgroups of $S$ containing $Q$. Under this identification, $H^0M$ is the restriction of $Z_F/Z_0$ by (2). Isomorphism (3) now follows since $(Z_F/Z_0)(P) = 0$ for all $P \not\leq Q$, and since there are no morphisms in $\mathcal{O}(\mathcal{F})$ from an object in the subcategory to an object not in it.

The existence and uniqueness of a centric linking system associated to $F$ now follow from [BLO2, Proposition 3.1].

We are now ready to show that each constrained fusion system is the fusion system of a group. The following proposition includes Proposition C.

**Proposition 4.3.** Let $\mathcal{F}$ be a constrained saturated fusion system over a $p$-group $S$. Then there is a unique finite $p'$-reduced $p$-constrained group $G$, containing $S$ as a Sylow $p$-subgroup, such that $\mathcal{F} = \mathcal{F}_S(G)$ as fusion systems over $S$. Furthermore, if $\mathcal{L}$ is a centric linking system associated to $\mathcal{F}$, then

(a) $G \cong \text{Aut}_\mathcal{L}(Q)$ for any subgroup $Q \lhd S$ which is $\mathcal{F}$-centric and normal in $\mathcal{F}$; and
(b) $\mathcal{L} \cong \mathcal{L}^c_S(G)$.

**Proof.** Using Proposition 4.2, fix a centric linking system $\mathcal{L}$ associated to $\mathcal{F}$. Let $\pi: \mathcal{L} \longrightarrow \mathcal{F}$ denote the canonical projection functor. By Lemma 3.7, any choice of “inclusion” morphisms $\iota_P \in \text{Mor}_\mathcal{L}(P, S)$ determines unique injections

$$\delta_{P,P'}: N_S(P, P') \longrightarrow \text{Mor}_\mathcal{L}(P, P'),$$

for all $\mathcal{F}$-centric subgroups $P, P' \leq S$, which satisfy the following conditions:

(i) $\pi(\delta_{P,P'}(g)) = c_g \in \text{Hom}_\mathcal{F}(P, P')$ for $g \in N_S(P, P')$;

(ii) $\delta_{P}(g) = \delta_{P}(g) = \in \text{Aut}_\mathcal{L}(P)$ for $g \in P$;

(iii) $\delta_{P,P'}(hg) = \delta_{P,P'}(h) \circ \delta_{P,P'}(g)$ for $g \in N_S(P, P')$ and $h \in N_S(P', P'');$ and

(iv) $\delta_{P,S}(1) = \iota_P$. 

Set $\iota_P = \delta_{P,P'}(1) \in \operatorname{Hom}_L(P, P')$ for all $P \leq P'$ containing $Q$. We think of these as the “inclusion morphisms” in $L$. By construction, $\iota_P = \iota_P$ and $\iota_P = \operatorname{Id}_P$ for all $P$, and $\iota_P = \iota_P \circ \iota_P$ whenever $P \leq P' \leq P''$.

The proposition follows from the following points, which will be proven in Steps 1–2.

(1) Assume $Q \triangleleft S$ is $\mathcal{F}$-centric and normal in $\mathcal{F}$, and $G = \operatorname{Aut}_L(Q)$. Then $G$ is $p'$-reduced and $p$-constrained; and we can identify $S$ with a subgroup of $G$ in such a way that $S \in \operatorname{Syl}_p(G)$ and $\mathcal{F} = \mathcal{F}_S(G)$.

(2) Assume $G$ is $p'$-reduced and $p$-constrained, and such that $S \in \operatorname{Syl}_p(G)$ and $\mathcal{F} = \mathcal{F}_S(G)$. Then $\mathcal{L} \cong \mathcal{L}_S(G)$. Also, if $Q \triangleleft S$ is any subgroup which is $\mathcal{F}$-centric and normal in $\mathcal{F}$, then $Q \triangleleft G$, and $G \cong \operatorname{Aut}_L(Q)$.

**Step 1:** Fix $Q \triangleleft S$ which is $\mathcal{F}$-centric and normal in $\mathcal{F}$, and set $G = \operatorname{Aut}_L(Q)$. Via the injection

$$\delta_{Q,Q} : S = N_S(Q) \longrightarrow \operatorname{Aut}_L(Q) = G,$$

we identify $S$ as a subgroup of $G$. Since $Q$ is fully normalized,

$$S/Z(Q) \cong \operatorname{Aut}_S(Q) \in \operatorname{Syl}_p(\operatorname{Aut}_\mathcal{F}(Q)),$$

where $\operatorname{Aut}_\mathcal{F}(Q) \cong G/Z(Q)$; and thus $S \in \operatorname{Syl}_p(G)$.

Let $P, P' \leq S$ be any pair of subgroups which contain $Q$. For any $f \in \operatorname{Mor}_L(P, P')$, there is (by Lemma 3.6) a unique “restriction” of $f$ to $Q$: a unique element $\gamma(f) \in G = \operatorname{Aut}_L(Q)$ such that $\iota_Q \circ \gamma(f) = f \circ \iota_Q$. These restrictions clearly satisfy the following two conditions:

(v) $\gamma(f \circ f') = \gamma(f') \cdot \gamma(f)$ for any $f' \in \operatorname{Mor}_L(P', P'')$, any $Q \leq P'' \leq S$; and

(vi) $\gamma(\delta_{P,P'}(x)) = x$ for all $x \in N_S(P, P')$.

Furthermore, by condition (C) in Definition 1.4, for each $g \in P$,

$$\delta_S(\pi(f)(g)) \circ f = f \circ \delta_P(g) \in \operatorname{Mor}_L(P, S).$$

Upon restriction to $Q$ (and applying (v) and (vi)), this gives the relation

$$\delta_{Q,Q}(\pi(f)(g)) \circ \gamma(f) = \gamma(f) \circ \delta_{Q,Q}(g) \in \operatorname{Aut}_L(Q) = G.$$

In other words, under the identification $S = \delta_{Q,Q}(S) \leq \operatorname{Aut}_L(Q) = G$, this shows that

(vii) $\gamma(f) \in N_G(P, P')$ and $c_{\gamma(f)} = \pi(f) \in \operatorname{Hom}_\mathcal{F}(P, P')$.

Now,

$$C_G(Q) = \operatorname{Ker}[\operatorname{Aut}_L(Q) \longrightarrow \operatorname{Aut}_\mathcal{F}(Q)] = Z(Q) :$$

the first equality by (vii) (applied with $P = P' = Q$, so $\gamma(f) = f$), and the second by condition (A) in Definition 1.4. Thus $Q$ is centric in $G$. This also shows that $O_{p'}(G) = 1$ (since $[O_{p'}(G), Q] = 1$), and hence that $G$ is $p'$-reduced and $p$-constrained.

We must show that $\mathcal{F} = \mathcal{F}_S(G)$. We first show that $\operatorname{Hom}_\mathcal{F}(P, P') \subseteq \operatorname{Hom}_G(P, P')$ for each $P, P' \leq S$. Since $Q$ is normal in $\mathcal{F}$, each morphism in $\operatorname{Hom}_\mathcal{F}(P, P')$ extends to a morphism in $\operatorname{Hom}_L(PQ, P'Q)$, and hence it suffices to work with subgroups $P, P' \geq Q$. In particular, $P$ and $P'$ are $\mathcal{F}$-centric in this case. For any $\varphi \in \operatorname{Hom}_\mathcal{F}(P, S)$, and any $f \in \operatorname{Mor}_L(P, S)$ such that $\pi(f) = \varphi$, $\gamma(f) \in N_G(P, P')$ and $\varphi = c_{\gamma(f)} \in \operatorname{Hom}_G(P, P')$ by (vii), and thus $\operatorname{Hom}_\mathcal{F}(P, P') \subseteq \operatorname{Hom}_G(P, P')$. 

Conversely, for any $P, P' \leq S$ and any $g \in N_G(P, P') = N_G(PQ, P'Q)$, we claim that $c_g \in \text{Hom}_\mathcal{F}(P, S) \subseteq \text{Hom}_G(P, S)$ (where the inclusion holds by the previous paragraph). Let $h \in N_G(P, S)$ be such that $\varphi = c_h$. Then $c_h|\mathcal{P} = \varphi|\mathcal{P} = c_g|\mathcal{P}$, so $h = gx$ for some $x \in C_G(\mathcal{P})$, and $C_G(Q) = Z(Q)$ as already shown. Since $x \in \mathcal{P}$, $c_x \in \text{Aut}_\mathcal{F}(P)$, so $c_g \in \text{Hom}_\mathcal{F}(P, S)$, and $c_g \in \text{Hom}_\mathcal{F}(P, P')$ since $c_g(P) = gPg^{-1} \leq P'$.

**Step 2:** Let $G$ be any finite $p'$-reduced $p$-constrained group such that $S \in \text{Syl}_p(G)$ and $\mathcal{F} = \mathcal{F}_S(G)$. Then $L \cong \mathcal{L}_S^G(G)$ by the uniqueness in Proposition 4.2.

Let $Q \triangleleft S$ be any subgroup normal in $\mathcal{F} = \mathcal{F}_S(G)$. Set $Q' = O_p(G)$; thus $C_G(Q') = Z(Q')$ by assumption. Since $Q$ is normal in $\mathcal{F}_S(G)$, for any $g \in G$, $c_g \in \text{Aut}_G(Q')$ extends to some $c_{g'} \in \text{Aut}_G(QQ')$; then $g^{-1}g' \in C_G(Q') = Z(Q')$, $g' \in N_G(QQ')$, and so $g \in N_G(QQ')$. This shows that $QQ' \triangleleft G$, a normal $p$-subgroup, and hence $Q \leq Q' = O_p(G)$. Hence for any $g \in G$, $c_g \in \text{Aut}_G(Q')$ restricts to an automorphism of $Q$ (since $Q$ is normal in $\mathcal{F}_S(G)$), so $g \in N_G(Q)$, and this shows that $Q \triangleleft G$.

In particular, if $Q$ is both $\mathcal{F}$-centric and normal in $\mathcal{F}$, then

$$\text{Aut}_L(Q) \cong \text{Aut}_L^G(Q) \cong N_G(Q)/O^p(C_G(Q)) = G/1 \cong G.$$  

It is in general not true, for a constrained fusion system $\mathcal{F}$ over a $p$-group $S$ and a finite group $G$ such that $S \in \text{Syl}_p(G)$ and $\mathcal{F} = \mathcal{F}_S(G)$, that $p$-subgroups of $S$ normal in $\mathcal{F}$ are also normal in $G$. For example, if $G = A_5$, $p = 2$, $S \in \text{Syl}_2(G)$, and $\mathcal{F} = \mathcal{F}_S(G)$, then $\mathcal{F}$ is a constrained fusion system, with $O_2(\mathcal{F}) = S \cong C_2^2$. Thus $S$ is normal in $\mathcal{F}$, but not in $G$, in this case. This shows the importance of assuming $G$ is $p'$-reduced and $p$-constrained. In the given example, the unique $2'$-reduced $2$-constrained group associated to $\mathcal{F}$ is $A_4$.
